The 16–Bit SCSI Bus Extender I/O Modules

Product Description

These modules, which mount at the right end of the SBB shelf (see Figure 1–2) are available for a single ended SCSI bus (BA35X–F series).

Figure 1–2 I/O Module Location

CXO5638A

There are two types of I/O modules — single channel and dual channel. The general rules for using the different I/O modules types are as follows:

- You can configure the single channel version (model BA35X–FA) for single bus, single shelf operation.
- You *cannot* configure single channel modules for dual channel, single shelf operation.
- When you use a tralink, you can configure single channel modules for single channel, multiple shelf operation.
- You can configure dual channel I/O modules (BA35X–FB) for dual buses (split buses) on a single shelf .

The 16–Bit SCSI Bus Extender I/O Modules

The dual channel modules have two 68–pin, VHDCI female connectors mounted on the front panel (see Figure 1–3). The upper connector is the channel A connector. The lower connector is the channel B connector. The single channel modules have only a channel A (upper) connector.

Figure 1–3 I/O Module Features

The I/O module top and bottom guides properly align the module in the shelf and with the backplane connector. When you install the I/O module the two spring steel mounting tabs expand and engage the shelf. The combination of the mounting tabs and the backplane connector ensures that the module is firmly seated in the shelf. To remove the module, press the tabs together until they disengage the shelf and pull the module out.

The 16-Bit SCSI Bus Extender I/O Modules

Mounted on the front of the module printed circuit board are the blower status LEDs (see Figure 1-4). These LEDs are either ON or FLASHING when there is a blower error or an overtemperature condition. The upper LED displays the status of the left blower. The lower displays the status of the right blower.

Figure 1-4 Front Panel Status LEDs

CX05712A

The blowers cool the I/O module by drawing ambient air in through the slots in the front and exhausting it out the rear of the shelf.

Shelf Cooling

The I/O module ensures that the SBBs and shelf are at the proper operating temperature by monitoring the operational status of the shelf blowers and sensing the ambient air temperature.

The two dual speed blowers (BA35X–MD) cool all the shelf components by drawing ambient air in through the front of the SBBs and exhausting it out the rear of the shelf. These blowers normally operate at low speed. Reduction of the air flow through the shelf or an increase in the ambient temperature may result in overheating. Such a condition can cause component failure or data corruption.

The I/O module ambient temperature circuitry monitors the air flowing through the module. Should the ambient air temperature exceed $32^{\circ}\text{C} + 2^{\circ}\text{C}$ ($90^{\circ}\text{F} + 3^{\circ}\text{F}$), this circuitry:

- Turns on both blower LEDs
- Causes both blower to switch to the high-speed mode to increase air flow through the shelf

When the I/O module circuitry detects a blower that is not operating or not operating at the correct RPM, this circuitry:

- Turns ON a LED on the I/O module front panel that identifies the defective blower
- Causes the operational blower to switch to the high–speed mode to increase air flow through the shelf, thereby maintaining the proper operating environment

Note

The shelf power supply status LEDs also display blower error conditions. However, they do not identify the defective blower, nor do they report ambient air temperature faults.

User-Defined Configurations

You use the 7 position shelf address switches (S3) and the 4 position SCSI bus termination switch (S4) located on the right side of the module (see Figure 1-5) to establish:

- Shelf device addresses (IDs)
- SCSI bus termination.

Figure 1-5 I/O Module Switches

SCSI Bus Termination Settings

Switch S4 (see Figure 1-6) determines the shelf bus termination:

- The top two switches (S4-1 and S4-2) control termination for channel A on both single and dual channel I/O modules.
- The bottom two switches (S4-3 and S4-4) control termination for channel B on dual channel I/O modules.

Note

Switches S4-3 and S4-4 have no function on a single channel I/O module.

Shelf Configuration

Unless specifically stated otherwise, the basic shelf configuration (see Figure 1-7) is as follows:

Figure 1-7 16-Bit SBB Shelf Backplane Termination

CXO4327A

- The 16-bit jumper module (BA35X-ME) is mounted on the backplane behind slot 6.
- You can store the *optional* 16-bit terminator module (BA35X-MF) behind slot 1.
- To identify the modules installed on the backplane remove the SBB from either slot 1 or slot 6.
 - The identification pin on a jumper module aligns with the top hole in the backplane.
 - The identification pin on a terminator module aligns with the bottom hole in the backplane.

Note

The module connector behind slot 1 is for storing the *unused* module. A module in this location has no affect on the shelf SCSI bus.

- The SCSI bus input is on channel A (connector JA1) for single channel I/O modules.

The 16–Bit SCSI Bus Extender I/O Modules

Note

There is no channel B connector on a single channel I/O module.

- The channel B connector on a dual channel module is either:
 - a SCSI bus input for a second host
- or
- a second bus

When you are using a dual channel I/O module, the channel B functions are determined by the module installed in slot 6:

- The shelf has one bus when the jumper module is installed in slot 6:
 - You can connect the single channel host to either the channel A or channel B connector.
 - You connect dual redundant hosts to the channel A and the channel B connectors.
- When the terminator module is installed in slot 6 the shelf has two buses. Connect the two hosts to the channel A and channel B connectors.

Table 1–3 Connector JB1 Functions

No. of Shelves	Bus Type	Shelf Position	Connector Function
1	Single	Last	Not used
1	Dual	First	Channel B Input

The 16–Bit SCSI Bus Extender I/O Modules

Use the following procedures to configure a shelf:

1. Remove power from the shelf and remove the I/O module.
2. Set switch S3 to establish the shelf addresses.
3. Set switch S4 to establish the SCSI bus termination for each channel.
4. Install the I/O module in the shelf.
5. Connect the external SCSI bus cables.

The 16–Bit SCSI Bus Extender I/O Modules

Configuring Two Shelves with a Single Bus

The features of this configuration include:

- The I/O module on each shelf terminates the bus on that shelf.
- The host or controller SCSI bus input is the channel A connector on the first shelf.
- The trilink link connector and a SCSI cable connect the SCSI bus input to the second shelf.

Note

For additional device address switch settings, see Appendix B.

Complete the following procedure, on *both shelves*, to establish a single bus, two shelf configuration:

1. Remove power from the shelf and remove both the I/O modules.
2. Set the SCSI bus termination switch on the *first* shelf for no termination.

CXO5720A

Configuring a Single Shelf with a Dual Bus

The features of this configuration include:

- The termination module behind slot 6 terminates both SBB shelf internal buses.
- The host SCSI bus inputs are both the channel A and the channel B connectors.

Note

For additional device address switch settings, see Appendix C.

Complete the following procedure to establish a single shelf dual bus configuration, complete the following procedure:

1. Remove power from the shelf and remove the I/O module.
2. Remove both blowers from the rear of the shelf
Install the termination module on the connector behind slot 6.
Store the jumper module on the connector behind slot 1.
3. Remove the I/O module and set the device address switch settings as shown in Table 1–6, or use one of the addresses listed in Appendix C.
4. Install the I/O module in the shelf.
5. Connect the external SCSI bus cables.
6. Assign device address and install SBBs.
7. Apply power and test the shelf for proper operation.

This configuration requires a dual channel I/O module (BA35X–FB) and the *optional* 16–bit SBB shelf termination module (BA35X–MF). The features of this configuration include:

- Both channel A and channel B are terminated by the *optional* 16–bit termination module (BA35X–MF) installed on the backplane behind slot 6.
- The channel A SCSI bus input connector is JA1.
- The channel B SCSI bus input connector is JB1.

Table 1–6 defines the SBB shelf SCSI bus length for this configuration and shows the default device address switch settings.

The diagram illustrates the physical layout of the SBB Shelf. It shows eight slots labeled Slot 7 through Slot 0. Slot 7 contains a Power supply. Slots 6 through 0 contain SCSI modules. The bus configuration is as follows: Slot 6 is Bus "A" (ID 6), Slot 5 is Bus "B" (ID 5), Slot 4 is Bus "A" (ID 4), Slot 3 is Bus "B" (ID 3), Slot 2 is Bus "A" (ID 2), Slot 1 is Bus "B" (ID 1), and Slot 0 is Bus "A" (ID 0). A Terminator module is located at the bottom of Slot 6. To the right of the slots is an I/O module with a switch panel. The switch panel has a "NO" position and seven numbered positions (1-7) with "OFF" and "ON" labels. A callout line points from the switch panel to the I/O module.

SCSI Bus Data

Table 1–7 defines the maximum data transfer rates and the maximum SCSI bus lengths when using a 16–bit extender I/O module. The cable lengths are rounded off to the nearest whole unit. The definition of data transfers rates are as follows:

- MT/s (megatransfers per second) is the repetitive rate at which words of data are transferred across a bus.
- MB/s (megabytes per second) is the number of megabytes per second (MB/s) is determined by the bus width (8– or 16–bit) and the number of bytes per word (1 or 2, respectively).

The 16-Bit SCSI Bus Extender I/O Modules

Table 1-7 Ultra SCSI Bus Parameters

Parameter	Specification
Transfer rates	20 MT/s — 40 MB/s
Maximum single ended shelf bus length	1 m (3.3 ft)
Maximum <i>Recommended</i> cable length	20 m (65.6 ft)
Maximum cable length	20 m (65.6 ft)

Note

Adding or removing devices to a shelf *does not* change the length of the shelf single ended bus. The only way to change the length of the shelf SCSI bus is configure the shelf as a dual bus.

SCSI Bus Cabling

You can connect the I/O module to the external SCSI bus using a combination of:

- VHDCI compatible cables.
- Adapter cables .
- Trilink connectors.
- VHDCI terminator blocks).

To select a compatible cable see Table 1-8.

The 16–Bit I/O Module

This chapter describes the SBB shelf 16-bit I/O module.

Figure 2–1 16–Bit I/O Module

CXO-5087A-MC

The 16–Bit I/O Module

Features

These I/O modules have the following features:

- Single channel, single shelf, single ended bus configuration
- Single channel, multiple shelf, single ended bus configuration
- Dual channel, single shelf, single ended bus configuration
- External 16–bit data bus connections
- Switch selectable device addresses (IDs)
- Overtemperature sensing, reporting, and automatic corrective action
- SBB shelf blower control to include error detection, reporting, and automatic corrective action

Product Description

These modules, (BA35X–MH) mount at the right end of the SBB shelf (see Figure 2–2).

Figure 2–2 I/O Module Location

The 16-Bit I/O Module

These modules have two 68-pin, high density, female connectors (see Figure 2-3). The top connector is the channel A connector. The front connector is the channel B connector.

The 7 position SCSI bus address switches determine the SBB shelf device addresses (device IDs).

Figure 2-3 I/O Module Features

CXO-4507A-MC

The I/O module top and bottom guides properly align the module in the shelf and with the backplane connector. When you install the I/O module, the two spring steel mounting tabs expand to engage the shelf. The combination of the mounting tabs and the backplane connector ensures that the module is firmly seated in the shelf. To remove the module, press the tabs together until they disengage the shelf and pull the module out.

The 16–Bit I/O Module

The blower status LEDs are also mounted on the I/O module *behind the front panel* (refer to Figure 2–3). These LEDs are either ON or FLASHING when there is a blower error or an overtemperature condition. You can easily view them through slots in the panel to the right of the connector. The top LED displays the status of the left blower. The bottom LED displays the status of the right blower. Both LEDs are on when there is an overtemperature condition.

The blowers cool the I/O module by drawing ambient air in through the slots in the module front and exhausting out the rear of the shelf.

Shelf Cooling

The I/O module ensures that the SBBs and shelf are at the proper operating temperature by monitoring the operational status of the shelf blowers and sensing the ambient air temperature.

The two dual speed blowers (BA35X–MD) cool all the shelf components by drawing ambient air in through the front of the SBBs and exhausting it out the rear of the shelf. These blowers normally operate at low speed. Reduction of the air flow through the shelf or an increase in the ambient temperature may result in overheating. Such a condition can cause component failure or data corruption.

The I/O module ambient temperature circuitry monitors the air flowing through the module. Should the ambient air temperature exceed $32^{\circ}\text{C} + 2^{\circ}\text{C}$ ($90^{\circ}\text{F} + 3^{\circ}\text{F}$), this circuitry:

- Turns on both blower LEDs
- Causes both blower to switch to the high-speed mode to increase air flow through the shelf

When the I/O module circuitry detects a blower that is not operating or not operating at the correct RPM, this circuitry:

- Turns ON a LED on the I/O module front panel that identifies the defective blower
- Causes the operational blower to switch to the high–speed mode to increase air flow through the shelf, thereby maintaining the proper operating environment

The 16–Bit I/O Module

Note

The shelf power supply status LEDs also display blower error conditions. However, they do not identify the defective blower, nor do they report ambient air temperature faults.

Shelf Configuration

Unless specifically stated otherwise, the basic shelf configuration is:

- The 16-bit jumper module (BA35X–ME) is mounted on the backplane behind slot 6.
- You can store the *optional* 16-bit terminator module (BA35X–MF) behind slot 1.
- To identify the modules installed on the backplane remove the SBB from either slot 1 or slot 6.
 - The identification pin on a jumper module aligns with the top hole in the backplane.
 - The identification pin on a terminator module aligns with the bottom hole in the backplane.
- The SCSI bus input is on channel A (connector JA1).

The channel B functions are determined by:

- The number of shelves (single or multiple)
- The SCSI bus type (single or dual)

The 16–Bit I/O Module

- The shelf position in the bus (for example, first, middle, last)

Note

The module connector behind slot 1 is for storing the *unused* module. A module in this location has no affect on the shelf SCSI bus.

SCSI Bus Data

Table 2–6 defines the maximum data transfer rates and the maximum SCSI bus lengths when using a 16-bit I/O module. The cable lengths are rounded off to the nearest whole unit. The definition of data transfers rates are as follows:

- MT/s (megatransfers per second) is the repetitive rate at which words of data are transferred across a bus.
- MB/s (megabytes per second) is the number of megabytes per second (MB/s) is determined by the bus width (8- or 16-bit) and the number of bytes per word (1 or 2, respectively).

Table 2–6 Fast 10 SCSI Bus Parameters

Parameter	Specification
Transfer rates	10 MT/s — 20 MB/s
Maximum single ended shelf bus length	1 m (3.3 ft)
Maximum single ended cable length	2 m (6.6 ft)

Note

Adding or removing devices to a shelf *does not* change the length of the shelf single ended bus. The only way to change the length of the shelf SCSI bus is to configure the shelf as a dual bus.

SCSI Bus Cabling

The input and output cables on the SCSI bus connect to the two connectors. The shelf SCSI bus configuration, single or dual, determines whether the connector functions as input connector or an output connector.

There are two cable variations available:

- High density cable with a 68-pin, right angle, connector on each end (see “BN21L–Series SCSI Cables,” on page 2–15)
- High density cable with a 68-pin, right angle, connector on one end and a 68-pin, standard connector on the other (see “BN21K–Series SCSI Adapter Cables,” on page 2–16)

The 8–Bit I/O Module

This chapter describes the 8-bit I/O module (see Figure 3–1). It explains how to install the I/O module in the 16-bit SBB shelf, and how to set the shelf small computer system interface (SCSI) addresses.

Figure 3–1 8–Bit I/O Module

The 8-Bit I/O Module

Features

These I/O modules have the following features:

- Single channel, single shelf, single ended bus configuration
- Dual channel, single shelf, single ended bus configuration
- External 8-bit data bus connections
- Overtemperature sensing, reporting, and automatic corrective action
- SBB shelf blower control to include error detection, reporting, and automatic corrective action

Product Description

The 8-bit I/O module is located on the right side of the shelf, next to slot 0 (see Figure 3-2).

Figure 3-2 16-Bit SBB Shelf with 8-Bit I/O Module

The 8-Bit I/O Module

On the front of the I/O module (see Figure 3–3) there are two 50-pin female connectors: channel A and channel B (see Figure 3–3). The blower status LEDs are also mounted on the front frame between the cable mounting slots. These LEDs are either ON or FLASHING when there is a blower error or an overtemperature condition. The top LED displays the status of the left blower. The bottom LED displays the status of the right blower. Both LEDs are on when there is an overtemperature condition.

The I/O module top and bottom guides properly align the module in the shelf and with the backplane connector. When you install the I/O module, the two spring steel mounting tabs expand to engage the shelf. The combination of the mounting tabs and the backplane connector ensures that the module is firmly seated in the shelf. To remove the module, press the tabs together until they disengage the shelf and pull the module out.

The blower status LEDs are also mounted on the I/O (refer to Figure 3–3). These LEDs are either ON or FLASHING when there is a blower error or an overtemperature condition. You can easily view them through slots in the panel to the right of the connector. The top LED displays the status of the left blower. The bottom LED displays the status of the right blower. Both LEDs are on when there is an overtemperature condition.

The 8-Bit I/O Module

The blowers cool the I/O module by drawing ambient air in through the slots in the module front and exhausting out the rear of the shelf.

Shelf Cooling

The I/O module ensures that the SBBs and shelf are at the proper operating temperature by monitoring the operational status of the shelf blowers and sensing the ambient air temperature.

The two dual speed blowers (BA35X–MD) cool all the shelf components by drawing ambient air in through the front of the SBBs and exhausting it out the rear of the shelf. These blowers normally operate at low speed. Reduction of the air flow through the shelf or an increase in the ambient temperature may result in overheating. Such a condition can cause component failure or data corruption.

The I/O module ambient temperature circuitry monitors the air flowing through the module. Should the ambient air temperature exceed $32^{\circ}\text{C} + 2^{\circ}\text{C}$ ($90^{\circ}\text{F} + 3^{\circ}\text{F}$), this circuitry:

- Turns on both blower LEDs
- Causes both blower to switch to the high-speed mode to increase air flow through the shelf

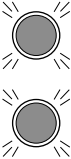

When the I/O module circuitry detects a blower that is not operating or not operating at the correct RPM, this circuitry:

- Turns ON a LED on the I/O module front panel that identifies the defective blower
- Causes the operational blower to switch to the high-speed mode to increase air flow through the shelf, thereby maintaining the proper operating environment

Note

The shelf power supply status LEDs also display blower error conditions. However, they do not identify the defective blower, nor do they report ambient air temperature faults.

Selecting a Bus Type

The 8-bit I/O module can operate as either a single or dual bus. The bus type is determined by —

- The location of SBB shelf jumper module.
- The location of the SBB shelf termination module.

The 8-Bit I/O Module

- The position of the I/O module address jumper.

Note

The bus type selected has no effect on the SCSI bus device addresses. These addresses cannot be changed.

Shelf Configuration

Unless specifically stated otherwise, the basic shelf configuration (see Figure 3–5) is:

Figure 3–5 16–Bit SBB Shelf Backplane Termination

- The 16-bit jumper module (BA35X–ME) is mounted on the backplane behind slot 6.
- You can store the *optional* 16-bit terminator module (BA35X–MF) behind slot 1.
- To identify the modules installed on the backplane remove the SBB from either slot 1 or slot 6.
 - The identification pin on a jumper module aligns with the top hole in the backplane.
 - The identification pin on a terminator module aligns with the bottom hole in the backplane.

Note

The module connector behind slot 1 is for storing the *unused* module. A module in this location has no affect on the shelf SCSI bus.

- The SCSI bus input is on channel A (connector JA1) for both single bus and dual bus configurations.
- For *single bus operation* install the *jumper module* on the backplane connector behind slot 6.

The 8-Bit I/O Module

- For *dual bus* operation install the *terminator module* on the backplane connector behind slot 6.

Single Bus, Single Shelf Addresses

The valid device addresses for a 16-bit I/O module on a single shelf with a single SCSI bus depends on the following factors:

- The controller configuration — single or dual redundant
- The settings of the 7 position SBB I/O module shelf address switch
- The settings of the 4 position SCSI bus termination switches on I/O modules with SCSI bus extender circuitry

Note

The information in this appendix applies to all 16-bit shelf I/O modules.

The information in this appendix *does not* apply to 8-bit shelf I/O modules.

Single Bus, Single Shelf Addresses

SCSI Bus Configuration Rules

The basic rules and considerations for configuring a SCSI bus and assigning device addresses (IDs) using an SBB I/O module address switch are as follows:

- No SCSI ID can be used more than once on any SCSI bus.
- All controller configurations reserve SCSI bus ID 7 for the primary controller. When you use a dual redundant configuration, SCSI bus ID 6 is reserved for the redundant controller.

Many of the shelf address switch settings automatically assign device ID 6 and 7 to a slot and often assigns one of the other addresses to more than one slot on the bus. There are many ways to compensate for these conflicts. Some of the more common ways to accomplish this include:

- Ensure that there is no conflict between an SBB and a controller by never inserting an SBB in a slot assigned device address 6 or 7.
- Ensure that when the same address occurs more than once on the same bus, that you install a device in only one of the slots.
- Use the SBB device address switch to assign an unused device ID to the SBB prior to installation.
- In most cases, the only viable solution is to not use a slot when there is a known device ID conflict. Using this solution can reduce the total number of devices on a single bus, single shelf configuration to only three or four SBBs.

Note

The alternate solution of using the SBB device address switch may not be viable, since most 3.5-inch SBBs *do not* have a device address switch.

The following sections list the DIGITAL-recommended shelf address switch settings that:

1. Do not use a device ID 7.
2. Do not use any device ID more than once on a single bus.
3. Do not use device ID 6 when there are two controllers on the bus.
4. List addresses for both single controller and dual controller configurations.

1. Connect the controller SCSI bus cable to the bus A connector on the SBB I/O module.
2. For the SBB I/O extender modules set the SCSI bus termination for one of the following bus configurations:

Caution

Connecting a cable to bus B connector disables the internal I/O module termination.

Glossary

AC–DC converter

A stand-alone device that converts an ac input to a dc voltage for the operation of table-top SCSI bus converters.

adapter

See SCSI signal bus converter.

backplane

The electronic printed circuit board mounted in the rear of the shelf. This board contains the terminators for the SBBs, power supplies, terminators, and other components.

blower assembly

An airflow device mounted in a StorageWorks shelf.

bus extender

Devices that couple bus segments together without any impact on the SCSI protocol, the firmware, or software are called bus extenders. The DWZZx family includes both single ended to differential and single ended to single ended bus extenders. The term extender is a general term that includes both “repeater” and “isolator.”

bus–path

The electrical connection directly between two terminators in a bus segment.

Glossary

bus–path connector

Any connector used to provide part of the bus–path.

bus segment

A SCSI bus segment consists of all the conductors and connectors required to attain signal line continuity between every driver, receiver, and two terminators for each signal. It is not necessary that a SCSI bus segment contain any initiators or targets, but it must have at least two devices attached. (Drivers and receivers may be part of extenders as well as part initiators and targets.)

The allowed length of a bus segment depends on the electrical loading, transmission media type, and data transfer rate. In many cases, heavier loading, smaller wires, and higher speeds demand shorter lengths. Loading is produced by increasing the number of devices in a given length of the bus, by using longer stubs, or higher capacitance devices.

bus segment types

There following are the SCSI bus segments types:

- Single ended (SE)
- High voltage differential (HVD)

The bus segment type is determined by the properties of the terminators used. Devices that do not have the same transceiver type as the terminators cannot operate in the segment defined by the terminators.

BUSY_GLITCH

The condition that may occur during the SCSI arbitration phase when nodes requesting service cause the BUSY signal to “bounce.”

cable connector

shelf I/O module

The circuit board that connects a 16-bit SBB shelf to a differential or single ended SCSI bus.

See also **differential I/O module** and **single ended I/O module**.

single ended I/O module

The 16-bit I/O module for extending an ultra SCSI bus between RAID subsystem shelves, such as the BA370-Series.

See also **shelf I/O Module**.

single ended SCSI bus

A bus in which each signal's logic level is determined by the voltage of a single wire in relation to ground.

Small Computer System Interface

See SCSI.

split bus

See dual bus.

STERMPOWER

Terminator power on a single ended SCSI bus.

See TERMPOWER.

StorageWorks

The DIGITAL set of enclosure products that allows customers to design and configure their own storage subsystem. Components include power, packaging, and interconnections in a StorageWorks shelf. SBBs and array controllers are integrated therein to form storage subsystems. System-level enclosures to house the shelves and standard mounting devices for SBBs are also included.

StorageWorks building bloc

See SBB.

stub

Any electrical path in a bus segment that is not part of the bus-path.

stub connection

The point where a stub meets the bus-path.

Stub connector

Any connector used to provide part of a stub.

table-top converter

A stand-alone, externally mounted SCSI bus converter that converts or extends a bus, or converts a differential bus to a single ended bus, or vice-versa. Usually requires an ac-dc power converter.

See also I/O module.

Glossary

terminator

Interconnect components that form the ends of the transmission lines in bus segments. A SCSI domain must have at least one segment and therefore at least two terminators, *except* for special cases where the electrical transmission lines are very short and only one termination or pull-up is required.

terminator connectors

Any connectors physically part of a terminator. It is not uncommon for terminators to have both stub and bus-path connectors.

TERMPower

The electrical current power required for SCSI bus terminators. This power may be supplied by an external SCSI bus, the shelf power supply or an ac-dc power converter.

transmission medium

an electrical conductor have bus termination on each end and possibly stubs. Common examples of media are cables, printed wiring boards, flex circuits, and connectors that create electrical connections between various combinations SCSI devices, bus extenders, and terminators.

ultra SCSI

A FAST 20 SCSI bus.

VHDCI

Very High Density Cable Interface. A 68-pin interface with connectors on 8 mm centers. Required for ultra SCSI.
