

HP C++

User's Guide for OpenVMS Systems

Order Number: AA-RPM8D-TE

June 2006

This manual contains information about developing HP C++ programs on OpenVMS systems and describes related language features.

Revision/Update Information: This revised guide supersedes the *HP C++ User's Guide for OpenVMS Systems* Order No. AA-RPM8C-TE, Version 7.1.

Operating System and Version: OpenVMS I64 Version 8.2 or higher
OpenVMS Alpha Version 7.3-2 or higher

Software Version: HP C++ Version 7.2 for OpenVMS Systems

This document was prepared using DECdocument, Version 3.3-1n.

Contents

Preface	xiii
1 Building and Running C++ Programs	
1.1 Using the DECTPU Text Editor	1-3
1.2 Using the Compiler	1-3
1.2.1 Compiler Command Qualifiers	1-4
1.2.2 Compiler Error Messages	1-4
1.3 Linking a Program (<i>Alpha only</i>)	1-5
1.3.1 CXXLINK Interactions with OpenVMS Linker Qualifiers ...	1-6
1.3.1.1 Command Parameters and Qualifier	1-6
1.3.2 Migrating from LINK to CXXLINK	1-6
1.3.3 Linking to the C++ Standard Library	1-7
1.3.4 Linking to the C++ Class Library	1-8
1.3.4.1 Linking Against the Class Library Object Library	1-8
1.3.4.2 Linking Against the Class Library Shareable Image	1-9
1.3.5 Linker Command Qualifiers	1-9
1.3.6 Linker Error Messages	1-9
1.4 Linking a Program (<i>I64 only</i>)	1-10
1.4.1 Linking Against C++ Class and Standard Library Shareable Images	1-11
1.4.2 Linking Against the Object Library (Linking /NOSYSSHARE)	1-12
1.5 Running a C++ Program	1-12
1.5.1 Run-Time Errors	1-13
1.5.2 Passing Arguments to the main Function	1-13
1.6 Name Demangling	1-15
1.6.1 Creating the Data File	1-16
1.6.2 Using the CXXDEMANGLE Facility	1-16
1.6.2.1 Command Qualifier	1-18
1.7 Performance Optimization Qualifiers	1-18
1.8 Improving Build Performance	1-19
1.9 Deploying Your Application	1-19

1.9.1	Redistribution of the DECC\$CTRL.OLB Object Library	1-19
1.9.2	Redistribution of the LIBCXXSTD.OLB Object Library	1-20

2 HP C++ Implementation

2.1	Implementation-Specific Attributes	2-1
2.1.1	#pragma Preprocessor Directive	2-1
2.1.1.1	#pragma [no]builtins	2-1
2.1.1.2	#pragma define_template Directive	2-2
2.1.1.3	#pragma environment Directive	2-2
2.1.1.4	#pragma extern_model Directive	2-4
2.1.1.5	#pragma extern_prefix Directive	2-9
2.1.1.6	#pragma function Directive	2-10
2.1.1.7	#pragma include_directory Directive	2-11
2.1.1.8	#pragma [no]inline Directive	2-11
2.1.1.9	#pragma intrinsic Directive	2-12
2.1.1.10	#pragma [no]member_alignment Directive	2-12
2.1.1.11	#pragma message Directive	2-13
2.1.1.12	#pragma module Directive	2-15
2.1.1.13	#pragma once Directive	2-16
2.1.1.14	#pragma pack Directive	2-16
2.1.1.15	#pragma [no]standard Directive	2-18
2.1.2	Predefined Macros and Names	2-18
2.1.3	Translation Limits	2-23
2.1.4	Numerical Limits	2-23
2.1.5	Argument-Passing and Return Mechanisms	2-24
2.2	Implementation Extensions and Features	2-24
2.2.1	Identifiers	2-24
2.2.1.1	External Name Encoding	2-25
2.2.1.2	Modifying Long Names	2-26
2.2.2	Order of Static Object Initialization	2-27
2.2.3	Integral Conversions	2-27
2.2.4	Floating-Point Conversions	2-27
2.2.5	Explicit Type Conversion	2-28
2.2.6	The sizeof Operator	2-28
2.2.7	Explicit Type Conversion	2-28
2.2.8	Multiplicative Operators	2-28
2.2.9	Additive Operators (§r.5.7)	2-29
2.2.10	Shift Operators (§r.5.8)	2-29
2.2.11	Equality Operators	2-29
2.2.12	Type Specifiers	2-29
2.2.13	asm Declarations (<i>Alpha only</i>)	2-29
2.2.14	Linkage Specifications	2-30

2.2.15	Class Layout	2-30
2.2.15.1	Structure Alignment	2-30
2.2.15.2	Bit-Fields	2-30
2.2.15.3	Access Specifiers	2-31
2.2.15.4	Class Subobject Offsets	2-31
2.2.16	Virtual Function and Base Class Tables	2-32
2.2.17	Multiple Base Classes	2-32
2.2.18	Temporary Objects	2-33
2.2.18.1	Lifetime of Temporary Objects	2-34
2.2.18.2	Nonconstant Reference Initialization with a Temporary Object	2-35
2.2.18.3	Static Member Functions Selected by Expressions Creating Temporary Objects	2-35
2.2.19	File Inclusion	2-35
2.2.20	Nested Enums and Overloading	2-40
2.2.21	Guiding Declarations	2-41
2.3	Alternative Tokens	2-42
2.4	Run-time Type Identification	2-43
2.5	Message Control and Information Options	2-43

3 C++ Language Environment

3.1	cname Headers	3-1
3.2	Using Existing C Header Files	3-2
3.2.1	Providing C and C++ Linkage	3-3
3.2.2	Resolving C++ Keyword Conflicts	3-3
3.2.3	Handling Scoping Issues	3-4
3.2.4	Support for <stdarg.h> and <varargs.h> Header Files	3-5
3.3	Using HP C++ with Other Languages	3-5
3.4	Linkage to Non-C++ Code and Data	3-6
3.5	How to Organize Your C++ Code	3-6
3.5.1	Code That Does Not Use Templates	3-6
3.5.2	Code That Uses Templates	3-7
3.5.3	Summary	3-11
3.5.4	Creating Libraries	3-11
3.6	Sample Code for Creating OpenVMS Shareable Images	3-12
3.7	Hints for Designing Upwardly Compatible C++ Classes	3-13
3.7.1	Source Compatibility	3-14
3.7.2	Link Compatibility	3-14
3.7.3	Run Compatibility	3-16
3.7.4	Additional Reading	3-16

4 Porting to I64 Systems

4.1	Compiler Considerations	4-2
4.1.1	Messages	4-2
4.1.2	Quotas	4-2
4.1.3	Dialect Changes	4-2
4.1.4	ABI/Object Model changes	4-3
4.1.5	Command-Line Qualifiers	4-3
4.1.6	Floating Point	4-7
4.1.7	Intrinsics and Bultins	4-9
4.1.8	ELF	4-10
4.1.9	Templates	4-11
4.1.10	Exceptions and Condition Handlers	4-12
4.1.10.1	Stack unwinding	4-12
4.1.10.2	Exceptions Not Caught	4-13
4.1.10.3	terminate() Incorrectly Called	4-13
4.1.10.4	Problem in unexpected() Behavior	4-16
4.2	Library Changes	4-18
4.2.1	Library Reorganization	4-18
4.2.1.1	Standard Library and Language Run-Time Support Library	4-18
4.2.1.2	Class Library	4-18
4.2.2	Language Run-Time Support Library	4-18
4.2.3	Class Library	4-19
4.2.4	Standard Library	4-19
4.2.4.1	Changes	4-19
4.2.4.2	Library Headers	4-19
4.2.4.3	Internal Library Headers and Macros	4-20
4.2.4.4	Known Issues and Restrictions	4-20
4.2.4.5	Differences Between Alpha and I64 Systems	4-20
4.3	CXXLINK Changes	4-27
4.4	Installation	4-27

5 Using Templates

5.1	Template Instantiation Model	5-2
5.2	Manual Template Instantiation	5-3
5.2.1	Mixing Automatic and Manual Instantiation	5-4
5.2.2	Instantiation Directives	5-4
5.2.2.1	#pragma define_template	5-4
5.2.2.2	#pragma instantiate and #pragma do_not_instantiate	5-8
5.2.3	Using Command Qualifiers for Manual Instantiation	5-9
5.3	Using Template Object Repositories (<i>Alpha only</i>)	5-10

5.3.1	Specifying Alternate Repositories	5-10
5.3.2	Reducing Compilation Time with the /TEMPLATE_DEFINE=TIMESTAMP Qualifier	5-11
5.3.3	Compiling Programs with Automatic Instantiation	5-12
5.3.4	Linking Programs with Automatic Instantiation	5-13
5.3.5	Creating Libraries	5-14
5.3.6	Multiple Repositories	5-15
5.4	Using COMDATS (<i>164 only</i>)	5-15
5.5	Advanced Program Development and Templates	5-16
5.5.1	Implicit Inclusion	5-16
5.5.2	Dependency Management	5-18
5.5.3	Creating a Common Instantiation Library	5-18
5.6	Command-Line Qualifiers for Template Instantiation	5-21
5.6.1	Instantiation Model Qualifiers	5-21
5.6.2	Other Instantiation Qualifiers	5-23
5.6.3	Repository Qualifiers	5-24

6 Handling C++ Exceptions

6.1	Compiling with Exceptions	6-1
6.2	Linking with Exceptions (<i>Alpha only</i>)	6-2
6.3	The terminate() and unexpected() Functions	6-2
6.4	C++ Exceptions and Other Conditions	6-3
6.5	C++ Exceptions and Signals (<i>Alpha only</i>)	6-4
6.6	C++ Exceptions with setjmp and longjmp	6-5
6.7	C++ Exceptions, lib\$establish and vaxc\$establish	6-6
6.8	Performance Considerations	6-6
6.9	C++ Exceptions and Threads	6-6
6.10	Debugging with C++ Exceptions (<i>Alpha only</i>)	6-8

7 The C++ Standard Library

7.1	Important Compatibility Information	7-2
7.1.1	/[NO]USING_STD Compiler Compatibility Qualifier	7-3
7.1.2	Pre-ANSI/ANSI Iostreams Compatibility	7-3
7.1.3	Support for pre-ANSI and ANSI operator new()	7-6
7.1.4	Overriding operator new() (<i>Alpha only</i>)	7-7
7.1.5	Overriding operator new() (<i>164 only</i>)	7-9
7.1.6	Support for Global array new and delete Operators	7-10
7.1.7	IOStreams Expects Default Floating-Point Format	7-11
7.2	How to Build Programs Using the C++ Standard Library	7-11
7.3	Optional Switch to Control Buffering (<i>Alpha only</i>)	7-12
7.4	Enhanced Compile-time Performance of ANSI Iostreams	7-12

7.5	Using RMS Attributes with iostreams	7-13
7.6	Upgrading from the Class Library to the Standard Library	7-13
7.6.1	Upgrading from the Class Library Vector to the Standard Library Vector	7-13
7.6.2	Upgrading from the Class Library Stack to the Standard Library Stack	7-14
7.6.3	Upgrading from the Class Library String Package Code	7-15
7.6.4	Upgrading from the Class Library Complex to the ANSI Complex Class	7-17
7.6.5	Upgrading from the Pre-ANSI iostream library to the HP C++ Standard Library	7-20

8 Using the OpenVMS Debugger

8.1	Debugging C++ Programs	8-1
8.1.1	Compiling and Linking in Preparation for Debugging	8-1
8.1.2	Debugger Support	8-2
8.1.3	Starting and Ending a Debugging Session	8-3
8.1.4	Features Basic to Debugging C++ Programs	8-3
8.1.4.1	Determining Language Mode	8-3
8.1.4.2	Built-In Operators	8-4
8.1.4.3	Constructs in Language and Address Expressions	8-5
8.1.4.4	Data Types	8-5
8.2	Using the OpenVMS Debugger with C++ Data	8-6
8.2.1	Nonstatic Data Members	8-6
8.2.1.1	Noninherited Data Members	8-7
8.2.1.2	Inherited Data Members	8-7
8.2.2	Reference Objects and Reference Members	8-7
8.2.3	Pointers to Members	8-8
8.2.4	Referencing Entities by Type	8-10
8.3	Using the OpenVMS Debugger with C++ Functions	8-11
8.3.1	Referring to Overloaded Functions	8-11
8.3.2	Referring to Destructors	8-12
8.3.3	Referring to Conversions	8-12
8.3.4	Referring to User-Defined Operators	8-13
8.3.5	Referring to Function Arguments	8-13
8.3.6	Calling C++ Member Functions from the Debugger	8-13

9 Using 64-bit Address Space

9.1	32-bit Versus 64-bit Development Environment	9-2
9.1.1	Model ANSI	9-3
9.1.2	Memory Allocators	9-3
9.1.3	64-bit Pointer Support in the C Run Time Library	9-4
9.2	Qualifiers and Pragmas	9-4
9.2.1	The /MODEL=ANSI Qualifier	9-5
9.2.2	The /POINTER_SIZE Qualifier	9-5
9.2.3	The __INITIAL_POINTER_SIZE Macro	9-6
9.2.4	Pragmas	9-6
9.3	Determining Pointer Size	9-7
9.3.1	Special Cases	9-8
9.3.2	Mixing Pointer Sizes	9-9
9.4	Header File Considerations	9-10
9.5	Prologue/Epilogue Files	9-10
9.5.1	Rationale	9-11
9.5.2	Using Prologue/Epilogue Files	9-11
9.6	Avoiding Problems	9-13
9.7	Reasons for Not Using Mixed Pointer Sizes	9-13

A Compiler Command Qualifiers

B Programming Tools

B.1	DEC Language-Sensitive Editor	B-1
B.1.1	Starting and Terminating an LSE Session	B-1
B.1.2	LSE Placeholders and Tokens	B-2
B.1.3	Compiling and Reviewing Source Code from an LSE Session	B-3
B.1.4	DEC Source Code Analyzer (SCA)	B-4

C Built-In Functions

C.1	Built-In Functions for Alpha Systems (<i>Alpha only</i>)	C-2
C.1.1	Translation Macros	C-2
C.1.2	Intrinsic Functions	C-3
C.1.3	Privileged Architecture Library Code Instructions	C-3
C.1.4	Other Builtins	C-24
C.2	Built-In Functions for I64 Systems (<i>I64 only</i>)	C-46
C.2.1	Builtin Differences on I64 Systems	C-46
C.2.2	Built-in Functions Specific to I64 Systems	C-48

D Class Library Restrictions

D.1	Class Library Restrictions	D-1
-----	--------------------------------------	-----

E Compiler Compatibility

E.1	Compatibility with Other C++ Compilers	E-1
E.2	Compatibility with Version 5.6 and Earlier	E-3
E.2.1	Language Differences	E-3
E.2.2	Implementation Differences	E-5
E.2.3	Using Templates	E-6
E.2.3.1	Linking with Version 5.n Instantiations	E-6
E.2.3.2	Linking Version 5.n Applications Against Version 6.n Repositories	E-7
E.2.4	Library Differences	E-7
E.3	Using Classes	E-7
E.3.1	Friend Declarations	E-7
E.3.2	Member Access	E-8
E.3.3	Base Class Initializers	E-8
E.4	Undefined Global Symbols for Static Data Members	E-8
E.5	Functions and Function Declaration Considerations	E-9
E.6	Using Pointers	E-9
E.6.1	Pointer Conversions	E-9
E.6.2	Bound Pointers	E-9
E.6.3	Constants in Function Returns	E-9
E.6.4	Pointers to Constants	E-10
E.7	Using typedefs	E-10
E.8	Initializing References	E-10
E.9	Using the switch and goto Statements	E-11
E.10	Using Volatile Objects	E-11
E.11	Preprocessing	E-12
E.12	Managing Memory	E-12
E.13	Size-of-Array Argument to delete Operator	E-12
E.14	Flushing the Output Buffer	E-13
E.15	Linking	E-13
E.16	Incrementing Enumerations	E-13
E.17	Guidelines for Writing Clean 64-Bit Code	E-13

Index

Preface

This manual contains information about developing and debugging HP C++ programs on OpenVMS systems, and includes information on other OpenVMS features and tools that work with the compiler.

Intended Audience

This manual is intended for experienced programmers who need to develop HP C++ programs on OpenVMS systems. Users of this manual should have a basic understanding of the C++ language and some familiarity with the Digital Command Language (DCL).

Structure of this Document

This manual is organized as follows:

- Chapter 1 shows how to create, compile, link, and run HP C++ programs.
- Chapter 2 describes features and characteristics that are specific to the HP C++ implementation.
- Chapter 3 describes guidelines and procedures for customizing your language environment.
- Chapter 4 describes how to make code used with other C++ implementations acceptable to the HP C++ compiler.
- Chapter 5 describes how to use templates with HP C++.
- Chapter 6 explains how to use C++ exception handling.
- Chapter 7 describes the HP C++ implementation of the C++ Standard Library.
- Chapter 8 explains how to use the OpenVMS Debugger with HP C++.
- Chapter 9 explains how to use 64-bit address space.
- Appendix A describes compiler command qualifiers.

- Appendix B provides information on using programming tools with HP C++.
- Appendix C describes built-in functions.
- Appendix D describes Class Library restrictions.

Associated Documents

The following documents contain information associated with topics in this manual:

- Stroustrup, Bjarne. *The C++ Programming Language, 3rd Edition*. Reading, Massachusetts: Addison-Wesley, 1997.
This text combines a user guide and language reference manual to provide an exhaustive introduction to the C++ programming language, including sophisticated language features. Where appropriate, section numbers shown in parentheses (for example, §r.2.3) refer to relevant portions of *The C++ Programming Language, 3rd Edition*.
- *HP C++ Class Library Reference Manual*
This manual describes a library of HP C++ classes.
- *HP C++ Installation Guide for OpenVMS Alpha*
This document supplies the information necessary to install HP C++ on OpenVMS Alpha systems.
- *HP C++ Installation Guide for OpenVMS I64*
This document supplies the information necessary to install HP C++ on OpenVMS I64 systems.
- *HP C Run-Time Library Reference Manual for OpenVMS Systems*
This library manual provides information, useful to HP C++ users, on the OpenVMS Run-Time Library (RTL) for C functions and macros, which include the ANSI C standard library. This manual also contains information about porting programs to and from other operating systems.

The C++ Programming Language, 3rd Edition and the *STL Tutorial and Reference Guide* are available only in printed form. Online copies are not available.

Related Documents

- Carroll, Martin D. and Margaret E. Ellis. *Designing and Coding Reusable C++*. Reading, Massachusetts: Addison-Wesley, 1995.
This text provides practical information for designing and implementing C++ programs.
- Myers, Scott. *Effective C++: 50 Specific Ways to Improve Your Programs and Designs, 3rd edition*. Reading, Massachusetts: Addison-Wesley, 1997.
- Myers, Scott. *More Effective C++: 35 New Ways to Improve Your Programs and Designs*. Reading, Massachusetts: Addison-Wesley, 1995.
These texts provide practical information for designing and implementing C++ programs.
- *International Standard ISO/IEC 14882*
Defines the C++ International Standard. The document is available for downloading at the ANSI Electronic Store (start at <http://www.ansi.org>).
The printed version is also available for purchase from the same web site. Choose “Catalogs/Standards Information”, then “ANSI-ISO-IEC Online Catalog”, then search for “14882”.

Conventions Used in this Manual

Table 1 lists the conventions used in this manual.

Table 1 Conventions Used in this Manual

Convention	Meaning
<code>class complex { . . };</code>	A vertical ellipsis indicates that some intervening program code or output is not shown. Only the more pertinent material is shown in the example.
<code>, . . .</code>	A horizontal ellipsis in a syntax description indicates that you can enter additional parameters, options, or values. A comma preceding the ellipsis indicates that successive items must be separated by commas.

(continued on next page)

Table 1 (Cont.) Conventions Used in this Manual

Convention	Meaning
The generic class ... The get() function ...	Monospaced type denotes the names of HP C++ language elements, and also the names of classes, members, and nonmembers. Monospaced type is also used in text to reference code elements displayed in examples.
<i>italic</i>	Italic type denotes the names of variables that appear as parameters or in arguments to functions, and also denotes book titles.
boldface	Boldface type in text indicates the first instance of terms defined in text.

Platform Labels

This guide contains information applicable to the HP OpenVMS operating system on Alpha and Intel Itanium processors. The information in this guide applies to both of these processors, except when specifically labeled as follows:

<i>(Alpha only)</i>	Specific to the OpenVMS operating system running on an Alpha processor.
<i>(I64 only)</i>	Specific to the OpenVMS operating system running on an Intel Itanium processor. On this platform, the product name of the operating system is OpenVMS for Industry Standard 64 for Integrity servers (abbreviated in this manual as OpenVMS I64 or I64).

New and Changed Features in C++ I64 Version 7.2

Some of the new or changed features supported by this version of the compiler are:

- 64-bit pointer support is added for C++ I64.
This support is compatible with the 64-bit pointer support in the C++ and C compilers for OpenVMS Alpha. It supports the same /POINTER_SIZE command-line qualifier, the __INITIAL_POINTER_SIZE predefined macro, and the same pragmas (#pragma pointer_size and #pragma required_pointer_size). Please see the V7.2 release notes for more information on 64-bit pointer support for the I64 compiler.
- Variadic macros are now supported.

This feature allows macros to take a variable number of arguments. It was added to HP C Version 6.4 and is supported by a number of other C and C++ compilers. This feature is available only when the value of the `/STANDARD` qualifier is `RELAXED` (the default), `MS`, or `GNU`.

- Support is added for generation of a new section type in the object file that maps mangled names to their original unmangled form.

Future versions of the linker will take advantage of this feature by using the demangled spelling of an identifier name for its error messages. In addition, the linker will be able to generate a new section in the linker map that shows mangled names and their corresponding unmangled original name.

- Prologue and epilogue file header processing is now supported in HP C++.
- The `__FUNCTION__` identifier is added.

`__FUNCTION__` is a predefined pointer to char defined by the compiler, which points to the name of the function as it appears in the source program. `__FUNCTION__` is same as `__func__` of C99.

New and Changed Features in Version 7.1

HP C++ Version 7.1 runs on OpenVMS Alpha and OpenVMS Integrity servers. The compiler behaves much the same on both systems, with some differences, primarily in the support for built-in functions, default floating-point representation, and predefined macros. These differences are noted in the relevant sections of this manual.

Some of the new or changed features supported by this version of the compiler on both Alpha and I64 systems are:

- `cname` header support is added (Section 3.1).

The C++ compiler implements section 17.4.1.2 - Headers [lib.headers] "C++ Headers for C Library Facilities" of the C++ Standard.

The implementation consists of 18 `<cname>` headers defined in the Standard (Chapter 3). As required by the C++ standard, the `<cname>` headers define C names in the `std` namespace.

The `/[NO]PURE_CNAME` qualifier is added to control insertion of the names by `<cname>` headers into the `std` namespace only (`/PURE_CNAME`), or into the `std` namespace and the global namespace (`/NOPURE_CNAME`).

- The `/[NO]FIRST_INCLUDE=(file[, . . .])` qualifier is added (Appendix A).

This qualifier includes the specified files before any source files. It corresponds to the *Tru64 UNIX* `-FI` switch.

- The `#pragma include_directory` preprocessor directive is added (Section 2.1.1.7).

This pragma is intended to ease DCL command-line length limitations when porting applications from POSIX-like environments built with makefiles containing long lists of `-I` options that specify directories to search for headers.

- Changes are made to the `/WARNING` qualifier and compiler messages (Section 2.5).

Changes to the `/WARNINGS` qualifier include bug fixes and improved compatibility with the C compiler. Some changes that might affect user compilations are:

- The `/WARNINGS=ENABLE=ALL` qualifier now enables all compiler messages including informational-level messages.
- The `/WARNINGS=INFORMATIONALS` qualifier continues to enable most informationals, but we recommend that `/WARNINGS=ENABLE=ALL` be used instead
- Using `/WARNINGS=INFORMATIONALS=<tag>` no longer enables all other informational messages.

Also, some compiler diagnostics might be different on Alpha and I64 systems, and some conditions detected on one platform might not be detected on the other.

- A new C++ front end is added to provide improved conformance to the C++ International Standard.
- Support for `/STANDARD=CFRONT` is retired.

Reader's Comments

You may send comments or suggestions regarding this manual, or any HP C++ document, by electronic mail to the following Internet address:

`c_docs@hp.com`.

Product Support

Premium support is available on a per-incident basis

http://www.hp.com/hps/perevent/pv_software.html

and annual contracts

http://www.hp.com/hps/os/os_openvms.html

from HP Services in the US and some other countries. In the US and Canada, call, toll-free, 1-800-354-9000. In other countries, support phone numbers are available on the web at:

<http://welcome.hp.com/country/us/en/wwcontact.html>

Free support is limited to bug reports that can be sent to

compaq_cxx.bugs@hp.com

Send a complete but short example reproducing the problem, including the following:

- Compiler and operating system versions
- All necessary sources (such as INCLUDE files and module sources)
- Data files
- Commands used to compile, link and run the program
- Expected results and incorrect results obtained

Please try to reduce the problem to as small a source as possible, because we may be unable to diagnose large applications.

We answer most quickly those problem reports that include a small but complete reproducible example, along with descriptions of the compile and link options used and the exact text of any diagnostic messages or other incorrect results. Reports that include only program fragments or involve very large applications generally will not be accepted.

Please note that this is not a “programming consulting service” and that you should have clear evidence of a product problem before contacting us. If you need consulting services, please contact HP Services.

1

Building and Running C++ Programs

C++ is an evolving language in which new features have recently replaced outmoded constructs. The C++ Standard Library provided with this release defines a complete specification of the C++ International Standard, with some differences, as described in the online release notes in:

```
SYS$HELP:CXX_RELEASE_NOTES.PS
```

When switching from a Version 5.*n* compiler, you might need to modify your source files, especially if you use the default language mode. In addition, language changes can affect the run-time behavior of your programs. If you want to compile existing source code with minimal source changes, compile using the `/STANDARD=ARM` qualifier. See Chapter 2.

This chapter provides information about basic steps in developing a C++ program on an OpenVMS system. These steps are shown in Figure 1-1.

To create and modify a C++ program, you must invoke a text editor. The OpenVMS system provides you with at least two text editors: VAX EDT (EDT) and the DEC Text Processing Utility (DECTPU). Another editor that you can use is the DEC Language-Sensitive Editor (LSE), which is sold separately (see Appendix B for more information on LSE). Use `.cxx` as the file type to signify that you are creating a C++ source program.

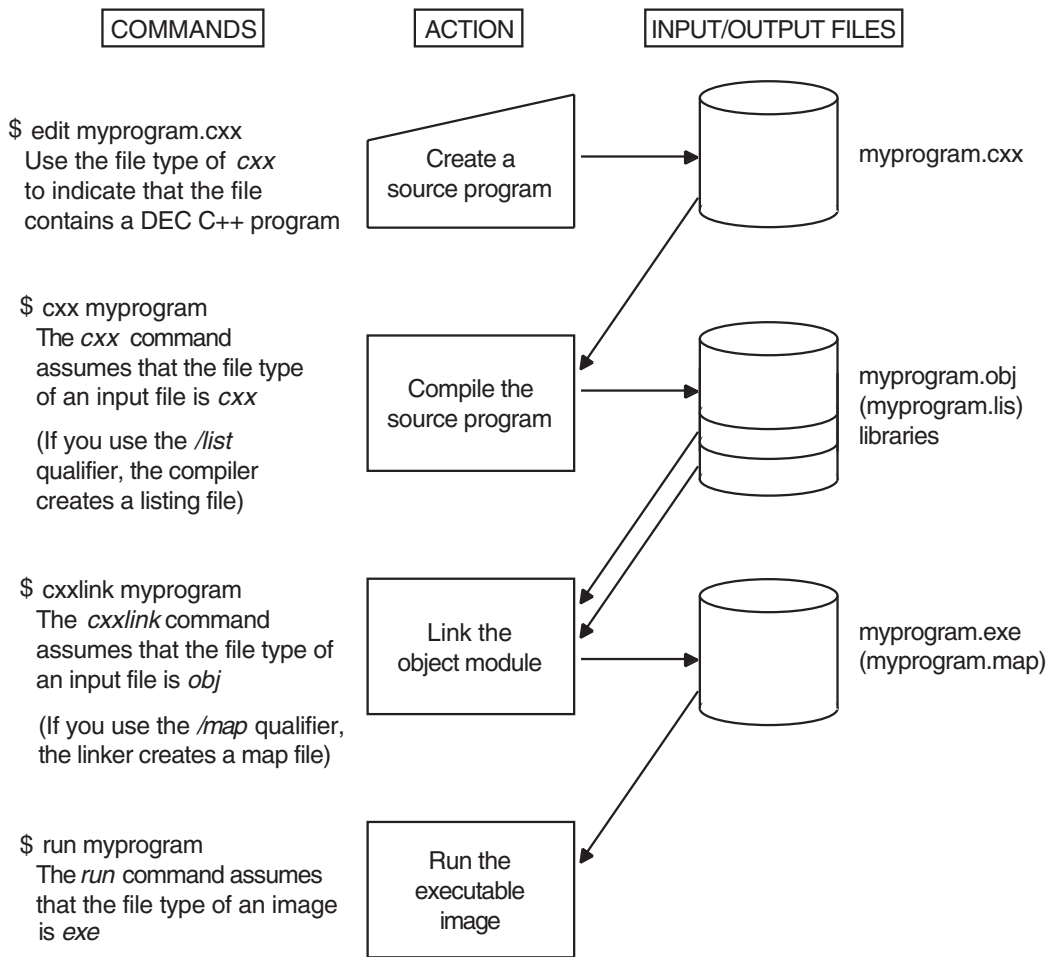

When you compile your program with the `cxx` command, you do not have to specify the file type; by default, C++ first looks for files with the `.cxx` type.

If the compilation succeeds, the compiler creates an object file with the type `.obj`. If the compiler detects errors, the system displays each error detected. You then reinvoke a text editor to make corrections.

When your program compiles successfully, you use the CXXLINK facility to create an executable image. Compiler and linker commands both take qualifiers, as described in Sections 1.2 and 1.3.

Building and Running C++ Programs

Figure 1-1 Steps in Developing a C++ Program

ZK-4979A-GE

When you have an executable image file, use the run command, or define a foreign command, to run your program. See Section 1.5 for more information on running image files.

Building and Running C++ Programs

1.1 Using the DECTPU Text Editor

1.1 Using the DECTPU Text Editor

With DECTPU, you have a choice of two editing interfaces, the Extensible Versatile Editor (EVE) or the DECTPU EDT Keypad Emulator. You can also create your own interfaces with DECTPU. At any time during your editing session you have access to online help.

When you invoke DECTPU to create a file, the editor automatically creates a journal file, which you can use to recover your keyboard entries if the system fails during an editing session. To initiate recovery, use the following command format:

```
edit/tpu/recover file-spec
```

The interactive editor interface, EVE, responds to all the common editing functions, invoked using the editing keypad, and supports more advanced functions that you type as commands on the EVE command line. For more information on using EVE, see the *Guide to VMS Text Processing*.

1.2 Using the Compiler

The compiler detects source program errors and shows each error either in a screen display or in the batch log file, depending on whether you run the compiler interactively or in batch mode. If the compilation succeeds, the compiler generates machine-language instructions from the source statements, and groups these instructions into an object module for the linker.

The compiler command `cxx` has the following format:

```
cxx[/qualifier...][ file-spec [/qualifier...]],...
```

You use qualifiers to instruct the compiler to perform some action. A qualifier placed immediately after the `CXX` command affects all the files listed. A qualifier placed immediately after a file specification affects only the preceding file, unless you concatenate your files. A qualifier placed on an individual file specification overrides a qualifier placed immediately after the `CXX` command.

If you include more than one file specification on the same line, use commas (,) or plus signs (+) as separators. For example:

```
$ cxx/list prog_1, prog_2, prog_3
```

A comma instructs the compiler to keep source files separate and to create an object file and a listing file for each source file. A plus sign instructs the compiler to concatenate each of the specified source files, and to create one object file and one listing file. Any qualifier specified for one file within a list of concatenated files affects all these files.

Building and Running C++ Programs

1.2 Using the Compiler

Note

Comma lists are not supported on I64 systems. Their use causes a fatal error.

1.2.1 Compiler Command Qualifiers

For a complete description of command line qualifiers, refer to Appendix A or to the online HELP.

1.2.2 Compiler Error Messages

If the compiler detects errors in your source code, the compiler signals these errors by displaying diagnostic messages in the following format:

```
%CXX-s-ident, message-text  
          at line number n in file name
```

s

Is the error severity, represented as follows:

- F** Fatal error. The compiler stops immediately without producing an object file. You cannot link the program until you correct this error.
- E** Error. The compiler proceeds, and possibly generates other messages, but does not produce an object file. You cannot link the program until you correct this error.
- W** Warning. The compiler takes some corrective action and produces an object file. However, to avoid unexpected results you must verify that the compiler's action is what you wanted.
- I** Information. The compiler informs you of specific actions taken. You need not take any action yourself regarding this message.
- S** Success.

ident

Is a mnemonic (abbreviation) of the message text.

message-text

Is the full text of a compiler diagnostic message explaining what happened.

n

Is an integer that gives you the number of the line where the error occurs. The number is relative to the beginning of the file or module in which the error occurs. The number appears on your terminal but not in listing files.

Building and Running C++ Programs

1.2 Using the Compiler

name

Is the name of the file or module in which the error occurs. The name appears on your terminal but not in listing files.

To be sure your program runs successfully, examine the diagnostic messages, evaluate error severity, and make any necessary corrections.

You can suppress certain information and warning diagnostic messages using the `#pragma message` preprocessor directive. For information about this directive, see Section 2.1.1.11.

1.3 Linking a Program *(Alpha only)*

This section describes how to link a C++ program on OpenVMS Alpha systems.

After your program or module successfully compiles, you **must** use the CXXLINK facility to combine your object modules into one executable image.

The CXXLINK facility is layered on the OpenVMS Linker utility and provides the ability to link your C++ application. Besides linking your C++ application, the CXXLINK facility completes the automatic template instantiation process; see Chapter 5 for details. CXXLINK also ensures that the Standard Template Library run-time support and the exception handling run-time support are linked into your application as needed.

CXXLINK uses the same command line format that you would use to invoke the OpenVMS Linker utility; thus, you can simply replace the LINK verb with CXXLINK in your command procedures. The CXXLINK command has the following format:

```
CXXLINK[/command-qualifier]... {file-spec/file-qualifier...},...
```

If you include more than one input file specification, use commas or plus signs as separators. By default, the linker creates an output file with the same name as the first input file and the file type `.exe`. If you want the output file to take the name of your main program, be sure to specify your main program file first. You can also use the `/EXECUTABLE=name.exe` qualifier on the CXXLINK command line to specify a name for the executable image.

Do not use the linker `cluster=` option to reference OpenVMS object modules that define global static objects. Using this option prevents the constructors and destructors for global static objects from being run during image activation and exit.

Building and Running C++ Programs

1.3 Linking a Program *(Alpha only)*

Caution

The OpenVMS Linker expects a function whose identifier is `main`. If a C++ program lacking a definition of `main` is inadvertently linked, then program execution begins at the first function seen by the linker.

1.3.1 CXXLINK Interactions with OpenVMS Linker Qualifiers

CXXLINK makes use of the OpenVMS Linker Utility's `LNK$LIBRARY` logical names to specific object libraries as input to the linker. If the CXXLINK command includes the `/USERLIBRARY` qualifier in any form, an informational message will be displayed and CXXLINK will list any required object libraries in a linker options file.

1.3.1.1 Command Parameters and Qualifier

In addition to the following qualifiers, the CXXLINK command accepts the same parameters and qualifiers as the OpenVMS Linker utility (see Section 1.3.5 for some of the more useful OpenVMS Linker qualifiers). CXXLINK-specific qualifiers are stripped off prior to calling the OpenVMS Linker utility and therefore have no effect on default device or directory specifications applied by the OpenVMS Linker facility.

Command Qualifiers	Defaults
<code>/[NO]LOG_FILE[=filename]</code>	<code>/NOLOG_FILE</code>
<code>/PREINST</code>	<code>/PREINST</code>
<code>/PRELINK=(option[,option2])</code>	See HELP.
<code>/REPOSITORY=(<i>writable-repository</i> [,<i>readonly-repository</i>,...])</code>	See HELP.
<code>/USE_LINK_INPUT[=filename]</code>	<code>/NOUSE_LINK_INPUT</code>
<code>/VERSION</code>	None.

For more information about CXXLINK qualifiers and parameters, type `HELP CXXLINK`.

1.3.2 Migrating from LINK to CXXLINK

Because a single CXXLINK command can invoke the OpenVMS Linker utility multiple times, you must not specify user mode (`DEFINE/USER_MODE`) logical names. If CXXLINK executes a second LINK command, the original `DEFINE/USER_MODE` logical name is not retained for that second command. Incorrect results can occur.

Building and Running C++ Programs

1.3 Linking a Program *(Alpha only)*

You should check command procedures that perform link operations of code generated by the C++ compiler for any `/USER_MODE` logical names that are intended to be in effect during a `LINK` operation. If you find any, you can modify the procedures `CXXLINK` in one of the following ways:

- Define the logical name without `/USER_MODE`. This means that the logical name should be deassigned, or its previous value reassigned, after the `CXXLINK` operation is completed to ensure that prior state is restored. Any `ON ERROR` cases that may be jumped to if the `CXXLINK` fails should check for and deassign or reassign the logical name if needed.
- Move the definition(s) into a separate command procedure. `CXXLINK` checks the logical name `CXX$LINK_INIT`, and if it is defined, executes the command procedure in its subprocess prior to executing any `LINK` command.

Consider the following procedure:

```
$ DEFINE/USER MYLIB MYAREA:MYLIB.OLB
$ LINK A,B,SYS$INPUT:/OPT
MYLIB/LIB
$
```

To have the procedure work with `CXXLINK`, modify it as follows:

```
$ CREATE CXX$LINK_INIT.COM
$ DEFINE MYLIB MYAREA:MYLIB.OLB
$EOD
$ DEFINE/USER CXX$LINK_INIT SYS$DISK:[]CXX$LINK_INIT.COM
$ LINK A,B,SYS$INPUT:/OPT
MYLIB/LIB
$!
$ DELETE CXX$LINK_INIT.COM;
```

Note that the `CXX$LINK_INIT` command procedure defines `MYLIB` without the `/USER_MODE` qualifier. This is because the command procedure is executed only once in the spawned process.

1.3.3 Linking to the C++ Standard Library

When you compile and link programs that use the C++ Standard Library, no special qualifiers are required. The C++ driver automatically includes the Standard Library run-time support on the link command, and automatic template instantiation is the default mode.

For example, to build a program called `prog.cxx` that uses the Standard Library, you enter the following command:

```
$ CXX prog.cxx
```

For detailed information about the Standard Library, refer to Chapter 7.

Building and Running C++ Programs

1.3 Linking a Program *(Alpha only)*

1.3.4 Linking to the C++ Class Library

Reusing code is a cornerstone of object-oriented programming. To minimize the time it takes to develop new applications, a set of reusable classes is an essential part of the HP C++ compiler environment. Class libraries offer a variety of predefined classes that enable you to work more efficiently.

For a detailed explanation of the class library packages supplied with the compiler, see the *HP C++ Class Library Reference Manual*, CXX_CLASSLIB.PS, in the SYS\$COMMON:[SYSHLP.CXX\$HELP] directory.

The Class Library has always been provided in shareable image format. Starting with OpenVMS Version 6.2, the Class Library is also provided in object library format.

Using the Class Library as an object library provides a functional advantage over using the shareable image. When your program redefines the global new and delete operators and uses the Class Library object library, the new and delete calls within the Class Library are directed to the new and delete operators defined by your program. On the other hand, when your program uses the Class Library shareable image, the new and delete calls within the Class Library always call the standard new and delete operators. Linking with the shareable image is the default method.

When you use the Class Library as a shareable image, the Class Library code resides in an image file in SYS\$SHARE and is shared by all C++ programs. This process has the advantages of: reducing the size of a program's executable image, decreasing the amount of disk space taken up by the program's image, and letting your program swap in and out of memory faster because of decreased size.

1.3.4.1 Linking Against the Class Library Object Library

To link against the Class Library object library on OpenVMS Version 6.2 or higher systems, you need to specify the /NOSYSSHR qualifier on your CXXLINK command. For example:

```
$ CXXLINK/NOSYSSHR my_program.obj
```

If your program defines nonlocal static objects whose constructors or destructors use any part of the Class Library, you need to ensure that the Class Library is initialized before your objects' constructors are invoked. (Note that this is not an issue when you link against the Class Library shareable image.) To guarantee this order of initialization, specify the Class Library initialization object module CXXL_INIT as the first module in your CXXLINK command. To do this, use a CXXLINK command similar to the following:

Building and Running C++ Programs

1.3 Linking a Program *(Alpha only)*

```
$ CXXLINK/NOSYSSHR/EXE=my_program SYS$SHARE:STARLET.OLB/INCLUDE=CXXL_INIT, -  
_ $ my_program.obj
```

If your program uses the task package, you must explicitly include the CMA shared library when you link /NOSYSSHR, as in the following example:

```
$ CXXLINK/NOSYSSHR my_program.obj, SYS$INPUT:/OPT -  
_ $ SYS$SHARE:CMA$LIB_SHR/SHARE  
^Z
```

1.3.4.2 Linking Against the Class Library Shareable Image

No special action is needed to link with the Class Library; simply specify the object modules and object libraries that you want to link. The linker automatically finds and resolves any references to objects in the Class Library when it searches the system-supplied shareable image library, SYS\$LIBRARY:IMAGELIB.OLB.

1.3.5 Linker Command Qualifiers

You can use qualifiers to modify OpenVMS Linker output and to invoke debugging and traceback facilities. The following list shows some of the most useful LINK command qualifiers that you can specify on your CXXLINK command. For a full discussion of the OpenVMS Linker, see the *OpenVMS Linker Utility Manual*.

Command Qualifiers	Defaults
/BRIEF	None.
/[NO]CROSS_REFERENCE	/NOCROSS_REFERENCE
/[NO]DEBUG	/NODEBUG
/[NO]EXECUTABLE[=file-spec]	/EXECUTABLE=first-object-file-name.exe
/FULL	None.
/[NO]MAP	/NOMAP (interactive) /MAP (batch)
/[NO]SHAREABLE	/NOSHAREABLE
/[no]TRACEBACK	/TRACEBACK

1.3.6 Linker Error Messages

If the OpenVMS Linker detects errors while linking object modules, the linker displays messages indicating the cause and severity of error. Because CXXLINK uses the OpenVMS Linker to link your C++ program, CXXLINK displays these linker messages. The linker does not produce an image file if errors or fatal errors occur (conditions with severities of E or F).

Some problems that commonly occur during linking are as follows:

- You try to link a program without defining every function that the program calls.

The linker responds by issuing warnings. For example:

Building and Running C++ Programs

1.3 Linking a Program *(Alpha only)*

`%LINK-W-USEUNDEF symbol-name`

A symbol name that you do not recognize could be a **mangled** name. Name mangling is the mechanism that the compiler uses to encode exceptionally long identifiers, including C++ function names. By default, CXXLINK displays such symbols in their demangled form. To see a symbol in its mangled form, use the `/PRELINK=NODEMANGLE` qualifier on your CXXLINK command. (See Section 1.6 for more information about name demangling.)

- You try to link a module that had warning or error messages during compilation.
To avoid unexpected results, verify that the linker's action is acceptable.
- You try to link a nonexistent module.
Check to see if the module exists (in the directory or library you expect it to be in) and is spelled correctly.
- You redefine a C RTL function, or override the global operators `new` or `delete`. For more information, see the `/[NO]PREFIX_LIBRARY_ENTRIES` Qualifier in Section 1.2.1.

For an explanation of linker messages, invoke the `HELP/MESSAGE` utility.

1.4 Linking a Program *(I64 only)*

This section describes how to link a C++ program on OpenVMS I64 systems.

After your program or module successfully compiles, you must use either the CXXLINK facility or OpenVMS Linker to combine your object modules into one executable image.

The CXXLINK facility is layered on the OpenVMS Linker utility and provides the ability to link your C++ application. On I64 systems, the CXXLINK facility accepts the same command qualifiers as CXXLINK on Alpha systems, including the full range of the Linker's command qualifiers that the CXXLINK facility passes to the Linker. For a description of Linker commands, see the *OpenVMS Linker Utility Manual*.

On I64 systems, the only benefit of using CXXLINK instead of the Linker is that CXXLINK reports non-mangled names of undefined and multiply-defined symbols. It does this by intercepting Linker diagnostics and converting mangled names reported by the Linker to their original names, using the information in the demangler database.

Building and Running C++ Programs

1.4 Linking a Program *(I64 only)*

The demangler database is a file created by the compiler. By default, it is created in a [.CXX_REPOSITORY] subdirectory of the current directory. For both the C++ compiler and CXXLINK, the location of the repository is controlled by the /REPOSITORY qualifier. For CXXLINK to correctly translate mangled names to their original, non-mangled counterparts, it is important to use the same repository for both compiling and linking.

Do not use the Linker CLUSTER= option to reference OpenVMS object modules that define global static objects. Using this option prevents the constructors and destructors for global static objects from being run during image activation and exit.

Caution

The OpenVMS Linker expects a function whose identifier is main. If a C++ program lacking a definition of main is inadvertently linked, then program execution begins at the first function seen by the linker.

1.4.1 Linking Against C++ Class and Standard Library Shareable Images

On I64 systems, the C++ Class and Standard Library, as well as the language run-time support library, are delivered as system shareable images in SYS\$LIBRARY:

CXXL\$011_SHR.EXE - class library image
CXXL\$RWRTL.EXE - standard library image
CXXL\$LANGRTL.EXE - language run-time support image

As system shareable images, these CXXL\$ images are part of the system library of shareable images, IMAGELIB.OLB, which is automatically searched by the Linker. Consequently, no special actions are required to link C++ applications against the class or standard library shareable image.

For example, if PROG.CXX uses a class from the C++ class or standard library, the following sequence of commands will compile, link, and run the program:

```
$ CXX PROG.CXX
$ CXXL PROG.OBJ ! (or LINK PROG.OBJ)
$ RUN PROG.EXE
```

Building and Running C++ Programs

1.4 Linking a Program *(164 only)*

1.4.2 Linking Against the Object Library (Linking /NOSYSSHARE)

In addition to being delivered as system shareable images, the C++ class, standard, and language run-time support libraries are also delivered in object form in the system object library STARLET.OLB, thus making it possible to link C++ applications /NOSYSSHARE.

The C++ libraries themselves do not impose any restrictions on linking /NOSYSSHARE. However, because they are layered on top of the C Run-Time Library, the rules for linking an application that references the C Run-Time Library /NOSYSSHARE do apply.

For example, when linking /NOSYSSHARE, you must explicitly include CMA\$TIS routines in the link by either linking against the CMA\$TIS_SHR.EXE shareable image or forcing the CMA\$TIS module from STARLET.OLB in the link. See the *HP C Run-Time Library Reference Manual* for more details.

Here are two examples of linking a C++ program /NOSYSSHARE:

```
$ CXXL/NOSYSSHARE PROG.OBJ, SYS$INPUT:/OPT
SYS$SHARE:CMA$TIS_SHR/SHARE
^Z

$ CXXL/NOSYSSHARE prog.obj, -
_ $ SYS$SHARE:STARLET.OLB/INCLUDE=CMA$TIS
```

1.5 Running a C++ Program

When your program successfully links, use the DCL RUN command to execute the image file. The RUN command has the following format:

```
RUN [/[NO]DEBUG] file-spec
```

/DEBUG
/NODEBUG

Determines whether you invoke the OpenVMS Debugger during run time. Use the /DEBUG qualifier to invoke the debugger if your image was not linked with the debugger. However, do not use the /DEBUG qualifier on images linked with the /NOTRACEBACK qualifier. Use the /NODEBUG qualifier if you linked your image with the /DEBUG qualifier and you do not want the debugger to prompt you. The default is RUN/DEBUG if you linked your image with the /DEBUG qualifier; otherwise, the default is RUN/NODEBUG.

For more information on debugging C++ programs, see Chapter 8.

Building and Running C++ Programs

1.5 Running a C++ Program

1.5.1 Run-Time Errors

When an error occurs during program execution, the OpenVMS condition handler terminates execution and displays messages and traceback information on the currently defined sys\$error device. In the symbolic stack dump traceback message, the condition handler lists the modules that were active when the error occurred, indicating the sequence in which the modules were called.

Traceback information is available at run time only for modules compiled with /DEBUG=TRACEBACK and linked with the /TRACEBACK qualifier in effect (the default for both compiler and linker commands). You should exclude traceback information only from thoroughly debugged program modules.

The traceback information makes reference to numbered lines that are listing lines in your program. If you include header files in the source file using the #include directive, the line numbers do not correspond to the source-file lines. To see the numbers that correspond to those referenced in the traceback information, generate a listing file using the /LIST qualifier to the compiler command.

1.5.2 Passing Arguments to the main Function

The main function in a C++ program can accept arguments from the command line from which it was invoked. The syntax for a main function is as follows:

```
int main(int argc,  
        char *argv[],  
        char *envp[])  
{  
    ...  
    return status;  
}
```

In this syntax, parameter *argc* is the count of arguments present in the command line that invoked the program, and parameter *argv* is a character-string array of the arguments. Parameter *envp* is the environment array, which contains process information such as the user name and controlling terminal. Parameter *envp* has no bearing on passing command-line arguments; its primary use in C++ programs is during exec and getenv function calls. For more information, see the *HP C Run-Time Library Reference Manual for OpenVMS Systems*.

Building and Running C++ Programs

1.5 Running a C++ Program

In the main function definition, the parameters are optional. However, you can access only the parameters that you define. You can define the main function in any of the following ways:

```
int main()
int main(int argc)
int main(int argc, char *argv[])
int main(int argc, char *argv[], char *envp[])
```

To pass arguments to the main function, you can use a DCL foreign command to point to the program, or you can define the logical name DCL\$PATH to point to an area containing the program.

To make use of DCL\$PATH in the previous example, the resulting program executable would have to be named "echo.exe".

You can then place echo.exe into a specific directory and point the logical name DCL\$PATH to it.

For example:

```
$ RENAME commarg.exe echo.exe
$ COPY echo.exe sys$login:
$ DEFINE DCL$PATH SYS$LOGIN:
```

The output would be identical to that shown in the previous example when a foreign command was used. To pass arguments to the main function, you must define the program as a DCL foreign command. When a program is defined and run as a foreign command, the parameter `argc` is always greater than or equal to 1, and `argv[0]` always contains the name of the image file.

The procedure for defining a foreign command involves using a DCL assignment statement to assign the name of the image file to a symbol that is later used to invoke the image. For example:

```
$ echo == "$ dsk$:commarg.exe" Return
```

The symbol `echo` is defined as a foreign command that invokes the image in `commarg.exe`. The definition of `echo` must begin with a dollar sign (\$) and include a device name.

For more information about the procedure for defining a foreign command, see the *HP OpenVMS DCL Dictionary*.

The following example shows a C++ program called `commarg.cxx`, which displays the command-line arguments that were used to invoke it:

Building and Running C++ Programs

1.5 Running a C++ Program

```
// This program echoes the command-line arguments.
#include <iostream.h>
main(int argc, char *argv[])
{
    int i;
    for (i = 0; i < argc; ++i)
        cout << i << " := >" << argv[i] << "<\n";
    return 0;
}
```

A sample output for this example is as follows:

```
$ echo Long "Day's" "Journey into Night" 
0 := >db7:commarg.exe;1<
1 := >long<
2 := >Day's<
3 := >Journey into Night<
```

DCL converts unquoted arguments on the command line to uppercase letters. However, the C RTL internally parses the altered command line and puts all unquoted arguments back in lowercase. This makes access to arguments in HP C++ programs compatible with C++ programs developed on other systems.

All arguments in the command line are delimited by spaces or tabs. Arguments with embedded spaces or tabs must be enclosed in quotation marks (" ").

1.6 Name Demangling

Because of the need to provide type-safe linking, HP C++ encodes type information in external function names. This encoding is called **name mangling**.

Mangled names can appear in diagnostic messages from commands such as CXXLINK/NOEXPAND or from the OpenVMS Linker utility. To enable users to decode (or demangle) these names, the compiler provides the CXXDEMANGLE facility. The CXXDEMANGLE facility translates mangled names into the names as they originally appeared in C++ source code.

To do the translation, CXXDEMANGLE uses a data file written by the compiler during compilation. The data file contains a mapping of mangled names to their demangled forms.

Building and Running C++ Programs

1.6 Name Demangling

1.6.1 Creating the Data File

Each time you compile a program, the compiler stores, in a data file, all the program's external symbols in their mangled and demangled forms. If the data file does not exist, the compiler creates the data file. Otherwise, the compiler appends information to the existing data file.

You can specify the name and location of the data file using the logical name `CXX$DEMANGLER_DB`. For example, if you want your data file to be named `MYCXXDB.DAT` in the `DISK1:[MYDIR]` directory, define the `CXX$DEMANGLER_DB` logical name as follows:

```
$ DEFINE CXX$DEMANGLER_DB DISK1:[MYDIR]MYCXXDB.DAT
```

If the `CXX$DEMANGLER_DB` logical name is not defined, the compiler uses the default file name `CXX$DEMANGLER_DB` in the writeable repository. Refer to Chapter 5 for details on how to specify the writeable repository.

1.6.2 Using the CXXDEMANGLE Facility

To demangle a symbol name, `CXXDEMANGLE` must use the same data file as the compiler used when it compiled the program containing the symbol.

Hence, if you defined the `CXX$DEMANGLER_DB` logical name when you compiled the program, you should also define the logical name when you use the `CXXDEMANGLE` facility.

Similarly, if you did not define the `CXX$DEMANGLER_DB` logical name but specified the `/REPOSITORY` qualifier during compilation, specify the same `/REPOSITORY` qualifier on your `CXXDEMANGLE` command.

If you did not specify the `/REPOSITORY` qualifier on your compile command, the compiler uses the data file in the default writeable repository. To use the `CXXDEMANGLE` facility in this case, either issue the `CXXDEMANGLE` command from the same directory where the compile command was issued, or specify the appropriate `/REPOSITORY` qualifier on your `CXXDEMANGLE` command.

`CXXDEMANGLE` provides both a command-line interface and an interactive interface, as follows:

- To use the command-line interface, enter the `CXXDEMANGLE` command followed by a comma-separated list of mangled symbol names. `CXXDEMANGLE` then displays the demangled form of each symbol and exits. The command-line interface has the following syntax:

```
CXXDEMANGLE mangled-symbol-name [, . . . ]
```

Building and Running C++ Programs 1.6 Name Demangling

The following example shows appropriate use of this syntax:

```
$ CXXDEMANGLE COPY_XPIPIPI
int * copy(int *, int *, int *)
$ CXXDEMANGLE COPY_XPPCPPCPPC, CXX$ADJCNTDFFRNCXPPP9MNS0IUE0NU
char ** copy(char **, char **, char **)
int * adjacent_difference(int *, int *, int *, minus<int >)
$
```

If you specify a mangled symbol name using the command-line interface and the symbol contains lowercase letters, you must place the symbol within quotes. For example:

```
$ CXXDEMANGLE "MyFunction__xic"
```

- To use the interactive interface, enter the CXXDEMANGLE command without specifying a symbol name. CXXDEMANGLE then waits for you to enter a symbol name in its mangled form. When you enter a symbol, CXXDEMANGLE displays the demangled form of the symbol and waits for you to enter another symbol, and so forth. To exit the interactive interface, enter Ctrl/Z. The syntax for the interactive interface is as following:

```
CXXDEMANGLE
mangled-symbol-name
[ ... ]
Ctrl/Z
```

The following example shows appropriate use of this syntax:

```
$ CXXDEMANGLE
COPY_XPIPIPI
int * copy(int *, int *, int *)
COPY_XPPCPPCPPC
char ** copy(char **, char **, char **)
CXX$ADJCNTDFFRNCXPPP9MNS0IUE0NU
int * adjacent_difference(int *, int *, int *, minus<int >)
Ctrl/Z
$
```

When you use the interactive interface, quotes are not necessary when entering mangled symbol names that contain lowercase letters.

If CXXDEMANGLE is unable to translate a mangled symbol name, it echoes the mangled symbol name.

Building and Running C++ Programs

1.6 Name Demangling

1.6.2.1 Command Qualifier

The CXXDEMANGLE command accepts a single qualifier, /REPOSITORY.

/REPOSITORY=(repository[, . . .])

Names the repository directories that contain the data files used by CXXDEMANGLE. The /REPOSITORY qualifier is ignored if you define the CXX\$DEMANGLE_DB logical name. See the preceding text for details.

1.7 Performance Optimization Qualifiers

The following compiler qualifiers can be used to improve performance. However, they can also change behavior for nonstandard-compliant programs:

- /[NO]ANSI_ALIAS—Specifies whether the compiler assumes the ANSI C aliasing rules to generate better optimized code. The default is /ANSI_ALIAS.
- /ASSUME=[NO]POINTERS_TO_GLOBALS—Controls whether the compiler can safely assume that global variables have not had their addresses taken in code that is not visible to the current compilation. The default is /ASSUME=POINTERS_TO_GLOBALS.
- /ASSUME=[NO]TRUSTED_SHORT_ALIGNMENT—Allows the compiler additional assumptions about the alignment of short types that, although naturally aligned, may cross a quadword boundary. The default is /ASSUME=NOTRUSTED_SHORT_ALIGNMENT.
- /ASSUME=[NO]WHOLE_PROGRAM—Tells the compiler that except for “well-behaved library routines”, the whole program consists only of the single object module being produced by this compilation. The optimizations enabled by /ASSUME=WHOLE_PROGRAM include all those enabled by /ASSUME=NOPOINTER_TO_GLOBALS and possibly other optimizations. The default is /ASSUME=NOWHOLE_PROGRAM.

You can use the /OPTIMIZE qualifier to improve performance. This qualifier will not change application behavior.

On I64 systems, the floating-point formats D_FLOAT, G_FLOAT, and F_FLOAT are emulated using IEEE_FLOAT. Because this can hinder performance, using the /FLOAT=IEEE_FLOAT default is recommended.

See Appendix A for detailed descriptions of these qualifiers.

Building and Running C++ Programs

1.8 Improving Build Performance

1.8 Improving Build Performance

Partitioning a large application into several shared libraries, which are then linked into an executable, is a useful technique for reducing link times during development. See Section 3.5 for more information.

1.9 Deploying Your Application

The HP C++ kit contains two Run-Time Library components that you might need to redistribute with your applications:

- C++ Standard Library Object Library (LIBCXXSTD)
- C Run-Time Object Library (DECC\$CRTL.OLB)

The next sections describe the method that developers must use to redistribute Run-Time Library components to user systems. Redistribution of other components on the HP C++ kit is prohibited. The redistribution rights set forth in the Software Product Description do not apply to the DECC\$CRTL.EXE or DECC\$CRTL.README files which are distributed with this kit.

1.9.1 Redistribution of the DECC\$CRTL.OLB Object Library

Redistribution of this library is only required by those applications which need to be linked during or after installation on an end user target system. If you link your application and ship either a shareable or executable image to your customers, then redistribution of the object library is not necessary. The linking process of your application causes those library modules to be incorporated into your resultant image.

There are two options that you can use to redistribute the DECC\$CRTL.OLB object library. The options are based on whether the library is needed after the installation is completed.

The first option is for applications which link during installation, but have no need for the object library once installation is completed. For that set of developers, we recommend placing DECC\$CRTL.OLB on your kit, but to link using the copy in VMI\$KWD and not issue a PROVIDE_FILE option which would move this file onto the system. In other words, the object library resides only on your kit, is used during installation to link your application, but is not placed onto the end user system.

The second option is for applications which do need the object library after installation is completed. For this class of applications, the object library should be placed in a product specific location on the target system and not in SYS\$LIBRARY. The contents of this object library must not be inserted into the SYS\$LIBRARY:STARLET.OLB library.

Building and Running C++ Programs

1.9 Deploying Your Application

1.9.2 Redistribution of the LIBCXXSTD.OLB Object Library

Redistribution of this library is only required by those applications which need to be linked during or after installation on an end user target system. If you link your application and ship either a shareable or executable image to your customers, then redistribution of the object library is not necessary. The linking process of your application causes those library modules to be incorporated into your resultant image.

There are two options that you can be used to redistribute the LIBCXXSTD.OLB object library. The options are based on whether the library is needed after the installation is completed.

The first option is for applications which link during installation, but have no need for the object library once installation is completed. For that set of developers, we recommend placing LIBCXXSTD.OLB on your kit, but to link using the copy in VMI\$KWD and not issue a PROVIDE_FILE option which would move this file onto the system. In other words, the object library resides only on your kit, is used during installation to link your application, but is not placed onto the end user system.

The second option is for applications that do need the object library after installation is completed. For this class of applications, the object library should be placed in a product specific location on the target system and not in SYS\$LIBRARY. The contents of this object library must not be inserted into the SYS\$LIBRARY:STARLET.OLB library.

HP C++ Implementation

This chapter discusses the features and characteristics specific to the HP C++ implementation, including pragmas, predefined names, numerical limits, and other implementation-dependent aspects of the language definition.

2.1 Implementation-Specific Attributes

This section describes pragmas, predefined names, and limits placed on the number of characters and arguments used in C++ programs.

2.1.1 #pragma Preprocessor Directive

The #pragma preprocessor directive is a standard method for implementing features that differ from one compiler to the next. This section describes pragmas specifically implemented in the C++ compiler for OpenVMS systems.

The following #pragma directives are subject to macro expansion. A macro reference can occur anywhere after the pragma keyword.

builtins	inline	linkage ¹	use_linkage ¹
dictionary	noinline	module	extern_model
member_alignment	message	define_template	extern_prefix

¹Not supported; specific to C

This manual displays keywords used with #pragma in lowercase letters. However, these keywords are not case sensitive.

2.1.1.1 #pragma [no]builtins

The #pragma builtins directive enables the C++ built-in functions that directly access processor instructions. If the pragma does not appear in your program, the default is #pragma nobuiltins.

C++ supports the #pragma builtins preprocessor directive for compatibility with VAX C, but it is not required.

HP C++ Implementation

2.1 Implementation-Specific Attributes

2.1.1.2 #pragma define_template Directive

The #pragma define_template directive instructs the compiler to instantiate a template with the arguments specified in the pragma. This pragma has the following syntax:

```
#pragma define_template identifier
```

For example, the following statement instructs the compiler to instantiate the template mytempl with the arguments arg1 and arg2:

```
#pragma define_template mytempl<arg1, arg2>
```

For more information on how to use templates with the #pragma define_template directive, see Section 5.2.

2.1.1.3 #pragma environment Directive

The #pragma environment directive offers a way to single-handedly set, save, or restore the states of *context* pragmas. This directive protects include files from contexts set by encompassing programs and protects encompassing programs from contexts that could be set in header files that the encompassing programs include.

On OpenVMS systems, the #pragma environment directive affects the following pragmas:

```
#pragma member_alignment  
#pragma message  
#pragma extern_model  
#pragma extern_prefix
```

This pragma has the following syntax:

```
#pragma environment command_line  
#pragma environment header_defaults  
#pragma environment restore  
#pragma environment save
```

command_line

Sets, as specified on the command line, the states of all the context pragmas. You can use this pragma to protect header files from environment pragmas that take effect before the header file is included.

header_defaults

Sets the states of all the context pragmas to their default values. This is almost equivalent to the situation in which a program with no command line options and no pragmas is compiled; except that this pragma sets the pragma message state to #pragma nostandard, as is appropriate for header files.

HP C++ Implementation

2.1 Implementation-Specific Attributes

save

Saves the current state of every pragma that has an associated context.

restore

Restores the current state of every pragma that has an associated context.

Without requiring further changes to the source code, you can use `#pragma environment` to protect header files from things like language extensions and enhancements that might introduce additional contexts.

A header file can selectively inherit the state of a pragma from the including file and then use additional pragmas as needed to set the compilation to non-default states. For example:

```
#ifndef __PRAGMA_ENVIRONMENT
#pragma __environment save 1
#pragma __environment header_defaults 2
#pragma member_alignment restore 3
#pragma member_alignment save 4
#endif

. /* contents of header file */
.
#endif
#pragma __environment restore
#endif
```

In this example:

- 1 Saves the state of all context pragmas
- 2 Sets the default compilation environment
- 3 Pops the member alignment context from the `#pragma member_alignment` stack that was pushed by `#pragma __environment save` (restoring the member alignment context to its preexisting state)
- 4 Pushes the member alignment context back onto the stack so that the `#pragma __environment restore` can pop the entry off

Thus, the header file is protected from all pragmas, except for the member alignment context that the header file was meant to inherit.

HP C++ Implementation

2.1 Implementation-Specific Attributes

2.1.1.4 #pragma extern_model Directive

The `#pragma extern_model` directive controls the compiler's interpretation of data objects that have external linkage. You can use this pragma to select the global symbol model to use for externs. The default is the relaxed refdef model.

After you select a global symbol model with `#pragma extern_model`, the compiler treats all subsequent declarations of objects of the extern storage class accordingly, until it encounters another `#pragma extern_model` directive.

The global symbol models are as follows:

- Common block model

In this model, all declarations are definitions and the linker combines all definitions with the same name into one definition. For Fortran program units, such extern variables appear as named COMMON blocks. The syntax is as follows:

```
#pragma extern_model common_block [(no)shr]
```

The `shr` and `nosh`r keywords determine whether the psects created for definitions are marked as shared or not shared. Fortran COMMON blocks normally have the shared attribute. If neither keyword is specified, the pragma acts as if `nosh`r was specified.

Note

The C language permits objects declared with the `const` type qualifier to be allocated in read-only memory, and when the C compiler allocates a psect for a `const` object, it marks that section as read-only.

This is not compatible with the C++ conventions because the C++ language permits objects with static storage duration to be initialized with values computed at run-time (before the main function gains control). When the C++ compiler allocates a psect for such a declaration, it marks the psect writable. Normally, only one compilation (the one responsible for initialization) will allocate a psect for a `const` object, and there is no problem.

But under the `common_block` extern model, the compilers will always allocate a psect for such a declaration, leading to a "conflicting attributes" warning from the linker if the same `const`-qualified declaration is processed by both C and C++. It is best to avoid use of the `common_block` extern model when `const` objects with external linkage are shared between C and C++. If the `common_block` model must be used, then the `const` type qualifier should be removed (for

HP C++ Implementation

2.1 Implementation-Specific Attributes

example, by preprocessor conditionals) from the declaration processed by the C compiler.

- Relaxed refdef model

This model is the default. Some declarations are references and some are definitions. Multiple uninitialized definitions for the same object are allowed and resolved into one by the linker. However, a reference requires that at least one definition exists. The syntax is as follows:

```
#pragma extern_model relaxed_refdef [(no)shr]
```

The `shr` and `noshr` keywords determine whether the psects created for definitions are marked as shared or not shared. If neither keyword is specified, the pragma acts as if `noshr` was specified.

- Strict refdef model

In this model, some declarations are references and some are definitions. It requires exactly one definition in the program for each symbol referenced. The syntax is as follows:

```
#pragma extern_model strict_refdef ["name"] [(no)shr]
```

If specified, *name* in quotes is the name of the psect for any definition.

The `shr` and `noshr` keywords determine whether the psects created for definitions are marked as shared or not shared. Neither keyword can be specified unless a name for the psect is given. If neither keyword is specified, the pragma acts as if `noshr` was specified.

- Globalvalue model

This model is like the strict refdef model except that these global objects have no storage; instead, global objects are link-time constant values. The syntax is as follows:

```
#pragma extern_model globalvalue
```

- Save

This pragma pushes the current extern model of the compiler onto a stack. The stack records all the information associated with the extern model, including the `shr` and `noshr` states and any quoted psect name.

The number of entries allowed in the `extern_model` stack is limited only by the amount of memory available to the compiler. The syntax is as follows:

```
#pragma extern_model save
```

- Restore

HP C++ Implementation

2.1 Implementation-Specific Attributes

This pragma pops the extern model stack of the compiler. The compiler's extern model is set as the state just popped off the stack. The stack records all the information associated with the extern model, including the `shr` and `nosh` states and any quoted psect name.

A warning message is issued if the program tries to pop an empty stack. Attempting to pop an empty stack does not change the compiler's extern state. The syntax is as follows:

```
#pragma extern_model restore
```

The `#pragma extern_model` directive has the following syntax:

```
#pragma extern_model model_spec [attr [, attr] ...]
```

model_spec is one of the following:

```
common_block
relaxed_refdef
strict_refdef "name"
strict_refdef (No attr specifications allowed)
globalvalue (No attr specifications allowed)
```

[*attr* [, *attr*] ...] are optional psect attribute specifications chosen from the following (at most one from each line):

```
gbl lcl      (Not allowed with relaxed_refdef)
shr nosh
wrt nowrt
pic nopic    (Not meaningful for Alpha)
ovr con
rel abs
exe noexe
vec novect
```

For OpenVMS Alpha systems: 0 byte 1 word 2 long 3 quad 4 octa 5 6 7 8 9
10 11 12 13 14 15 16 page

For OpenVMS VAX systems: 2 long 3 quad 4 octa 9 page

The last line of attributes are numeric alignment values. When a numeric alignment value is specified on a section, the section is given an alignment of two raised to that power.

On OpenVMS Alpha systems, the `strict_refdef "name"` `extern_model` can also take the following psect attribute specifications:

- `noreorder` — causes variables in the section to be allocated in the order they are defined.
- `natalgn` — has no effect on OpenVMS systems.

HP C++ Implementation

2.1 Implementation-Specific Attributes

It does, however, change the behavior on Tru64 UNIX systems: when specified, `natural` causes the global variables defined within the section to be allocated on their natural boundary. Currently, all global variables on Tru64 UNIX systems are allocated on a quadword boundary. When the `natural` attribute is specified, the compiler instead allocates the variable on an alignment that is natural for its type (chars on byte boundaries, ints on longword boundaries, and so on).

Specifying the `natural` attribute also enables the `noreorder` attribute.

Note

Use of the `natural` attribute can cause a program to violate the Tru64 UNIX Calling Standard. The calling standard states that all global variables must be aligned on a quadword boundary. Therefore, variables declared in a `natural` section should only be referenced in the module that defines them.

Table 2-1 lists the attributes that can be applied to program sections.

Table 2-1 Program-Section Attributes

Attribute	Meaning
PIC or NOPIC	The program section or the data these attributes refers to does not depend on any specific virtual memory location (PIC), or else the program section depends on one or more virtual memory locations (NOPIC).
CON or OVR	The program section is concatenated with other program sections with the same name (CON) or overlaid on the same memory locations (OVR).
REL or ABS	The data in the program section can be relocated within virtual memory (REL) or is not considered in the allocation of virtual memory (ABS).
GBL or LCL	The program section is part of one cluster, is referenced by the same program section name in different clusters (GBL), or is local to each cluster in which its name appears (LCL).
EXE or NOEXE	The program section contains executable code (EXE) or does not contain executable code (NOEXE).

(continued on next page)

HP C++ Implementation

2.1 Implementation-Specific Attributes

Table 2–1 (Cont.) Program-Section Attributes

Attribute	Meaning
WRT or NOWRT	The program section contains data that can be modified (WRT) or data that cannot be modified (NOWRT).
RD or NORD	These attributes are reserved for future use.
SHR or NOSHR	The program section can be shared in memory (SHR) or cannot be shared in memory (NOSHR).
USR or LIB	These attributes are reserved for future use.
VEC or NOVEC	The program section contains privileged change mode vectors (VEC) or does not contain those vectors (NOVEC).
COM or NOCOM	The program section is a conditionally defined psect associated with a conditionally defined symbol. This is the type of psect created when you declare an uninitialized definition with <code>extern_model relaxed_refdef</code> .

See the *OpenVMS Linker Utility Manual* for more complete information on each.

The default attributes are: `noshr`, `rel`, `noexe`, `novect`, `nopic`.

For `strict_refdef`, the default is `con`. For `common_block` and `relaxed_refdef`, the default is `ovr`.

The default for `wrt/nowrt` is determined by the first variable placed in the psect. If the variable has the `const` type qualifier (or the `readonly` modifier), the psect is set to `nowrt`. Otherwise, it is set to `wrt`.

Restrictions on Setting Psect Attributes

Be aware of the following restriction on setting psect attributes.

The `#pragma extern_model` directive does not set psect attributes for variables declared as tentative definitions in the `relaxed_refdef` model. A tentative definition is one that does not contain an initializer. For example, consider the following code:

```
#pragma extern_model relaxed_refdef long
int a;
int b = 6;
#pragma extern_model common_block long
int c;
```

HP C++ Implementation

2.1 Implementation-Specific Attributes

Psect A is given octaword alignment (the default) because a is a tentative definition. Psect B is correctly given longword alignment because it is initialized and is, therefore, not a tentative definition. Psect C is also given longword alignment because it is declared in an `extern_model` other than `relaxed_refdef`.

Note

The psect attributes are normally used by system programmers who need to perform declarations normally done in macro. Most of these attributes are not needed in normal C programs. Also, notice that the setting of attributes is supported only through the `#pragma` mechanism, and not through the `/EXTERN_MODEL` command-line qualifier.

2.1.1.5 `#pragma extern_prefix` Directive

The `#pragma extern_prefix` directive controls the compiler's synthesis of external names, which the linker uses to resolve external name requests. When you specify `#pragma extern_prefix` with a string argument, the compiler prepends the string to all external names produced by the declarations that follow the pragma specification.

This pragma is useful for creating libraries where the facility code can be attached to the external names in the library.

The syntax is as follows:

```
                "string"
#pragma extern_prefix  save
                    restore
```

"string"

Prepends the quoted string to external names in the declarations that follow the pragma specification.

save

Saves the current pragma prefix string.

restore

Restores the saved pragma prefix string.

The default external prefix, when none has been specified by a pragma, is the null string. The recommended use is as follows:

```
#pragma extern_prefix save
#pragma extern_prefix "prefix-to-prepend-to-external-names"
```

HP C++ Implementation

2.1 Implementation-Specific Attributes

```
... some declarations and definitions ...  
#pragma extern_prefix restore
```

When an `extern_prefix` is in effect and you are using `#include` to include header files, but do not want the `extern_prefix` to apply to extern declarations in the header files, use the following code sequence:

```
#pragma extern_prefix save  
#pragma extern_prefix "  
#include ...  
#pragma extern_prefix restore
```

Otherwise, the external identifiers for definitions in the included files will be prepended with the external prefix.

All external names prefixed with a nonnull string using `#pragma extern_prefix` are converted to uppercase letters regardless of the setting of the `/NAMES` qualifier.

The compiler treats `#pragma extern_prefix` independently of the `/PREFIX_LIBRARY_ENTRIES` qualifier. The `/PREFIX_LIBRARY_ENTRIES` qualifier affects only ANSI and C Run-Time Library (RTL) entries; the `extern_prefix` pragma affects external identifiers for any externally visible name.

2.1.1.6 #pragma function Directive

The `#pragma function` directive specifies that calls to the specified functions will occur in the source code. You normally use this directive in conjunction with `#pragma intrinsic`, which affects specified functions that follow the pragma directive. The effect of `#pragma intrinsic` on a given function continues to the end of the source file or until a `#pragma function` directive occurs, specifying that function.

The `#pragma function` directive has the following syntax:

```
#pragma function (function1 [, function2, ... ])  
#pragma function ()
```

You cannot specify this pragma with empty parentheses. To disable all intrinsic functions, specify the `/OPTIMIZE=NOINTRINSICS` qualifier on the command line.

HP C++ Implementation

2.1 Implementation-Specific Attributes

2.1.1.7 `#pragma include_directory` Directive

The effect of each `#pragma include_directory` is as if its string argument (including the quotes) were appended to the list of places to search that is given its initial value by the `/INCLUDE_DIRECTORY` qualifier, except that an empty string is not permitted in the pragma form.

The `#pragma include_directory` directive has the following syntax:

```
#pragma include_directory <string-literal>
```

This pragma is intended to ease DCL command-line length limitations when porting applications from POSIX-like environments built with makefiles containing long lists of `-I` options that specify directories to search for headers. Just as long lists of macro definitions specified by the `/DEFINE` qualifier can be converted to `#define` directives in a source file, long lists of places to search specified by the `/INCLUDE_DIRECTORY` qualifier can be converted to `#pragma include_directory` directives in a source file.

Note that the places to search, as described in the help text for the `/INCLUDE_DIRECTORY` qualifier, include the use of POSIX-style pathnames, for example `"/usr/base"`. This form can be very useful when compiling code that contains POSIX-style relative pathnames in `#include` directives. For example, `#include <subdir/foo.h>` can be combined with a place to search such as `"/usr/base"` to form `"/usr/base/subdir/foo.h"`, which will be translated to the filespec `"USR:[BASE.SUBDIR]FOO.H"`

This pragma can appear only in the main source file or in the first file specified on the `/FIRST_INCLUDE` qualifier. Also, it must appear before any `#include` directives.

2.1.1.8 `#pragma [no]inline` Directive

The `#pragma inline` directive expands function calls inline. The function call is replaced with the function code itself.

The `#pragma inline` directive has the following syntax:

```
#pragma inline (id,...) #pragma noline (id,...)
```

If a function is named in an inline directive, calls to that function will be expanded as inline code, if possible.

If a function is named in a noline directive, calls to that function will not be expanded as inline code.

If a function is named in both an inline and a noline directive, an error message is issued.

HP C++ Implementation

2.1 Implementation-Specific Attributes

For calls to functions named in neither an inline nor a noinline directive, C++ expands the function as inline code whenever appropriate as determined by a platform-specific algorithm.

2.1.1.9 #pragma intrinsic Directive

The #pragma intrinsic directive specifies that calls to the specified functions are intrinsic. Intrinsic functions are functions in which the compiler generates optimize code in certain situations, possibly avoiding a function call.

The #pragma intrinsic directive has the following syntax:

```
#pragma intrinsic (function1[,function2, ... ])
```

You can use this directive to make intrinsic the default form of functions that have intrinsic forms. The following functions have intrinsic forms:

```
abs  
fabs  
labs  
alloca
```

You can use the #pragma function directive to override the #pragma intrinsic directive for specified functions.

The function must have a declaration visible at the time the compiler encounters the #pragma intrinsic directive. The compiler takes no action if the compiler does not recognize the specified function name as an intrinsic.

2.1.1.10 #pragma [no]member_alignment Directive

By default, the compiler for OpenVMS systems aligns structure members so that members are stored on the next boundary appropriate to the type of the member; that is, bytes are on the next byte boundary, words are on the next word boundary, and so on.

You can use the #pragma member_alignment directive to specify structure member alignment explicitly. For example, using #pragma member_alignment aligns a long member variable on the next longword boundary, and it aligns a short member variable on the next word boundary.

Using #pragma nomember_alignment causes the compiler to align structure members on the next byte boundary regardless of the type of the member. The only exception to this is for bit-field members.

If used, the nomember_alignment pragma remains in effect until the compiler encounters the member_alignment pragma.

To save and restore the current setting of the member_alignment pragma, you can use the member_alignment save and member_alignment restore pragmas.

HP C++ Implementation

2.1 Implementation-Specific Attributes

To affect the member alignment of the entire module, use the `/MEMBER_ALIGNMENT` qualifier. For information about this qualifier, see Section 2.1.1.10.

2.1.1.11 `#pragma message` Directive

The `#pragma message` directive controls the kinds of individual diagnostic messages or groups of messages that the compiler issues. Use this pragma to override any command-line options specified by the `/WARNINGS` qualifier, which affects the types of messages the compiler issues.

Default severities used by the compiler can be changed only if they are informationals, warnings, or discretionary errors. Attempts to change more severe severities are ignored. If a message severity has not been altered by the command line and is not currently being controlled by a pragma, the compiler checks to see whether the message severity should be changed because of the “quiet” state. If not, the message is issued using the default severity.

Error message severities start out with command-line severities applied to default compiler severities. Pragma message severities are then applied. In general, pragma severities override command-line severities, which override default severities. The single exception to this is that command-line options can always be used to downgrade messages. However, command-line qualifiers cannot be used to raise the severity of messages currently controlled by pragmas.

The `#pragma message` directive has the following syntax:

```
#pragma message disable (message-list)
#pragma message enable (message-list)
#pragma message error (message-list)
#pragma message fatal (message-list)
#pragma message informational (message-list)
#pragma message warning (message-list)
#pragma message restore
#pragma message save
```

disable

Suppresses the compiler-issued messages specified in the *message-list* argument. The *message-list* argument can be any one of the following:

- A single message identifier
- The keyword ALL (all messages issued by the compiler)
- A single message identifier enclosed in parentheses
- A comma-separated list of message identifiers enclosed in parentheses

HP C++ Implementation

2.1 Implementation-Specific Attributes

A message identifier is the name immediately following the message severity code letter. For example, consider the following message:

```
%CXX-W-MISSINGRETURN, Non-void function "name" does not contain a return statement
```

The message identifier is `MISSINGRETURN`. To prevent the compiler from issuing this message, use the following directive:

```
#pragma message disable MISSINGRETURN
```

The compiler lets you disable a discretionary message if its severity is warning (W), informational (I), or error (E) at the time the message is issued. If the message has severity of fatal (F), the compiler issues it regardless of instructions not to issue messages.

enable

Enables the compiler to issue the messages specified in the *message-list* argument.

errors

Sets the severity of each message in the message list to Error.

fatals

Sets the severity of each message in the message list to Fatal.

informationals

Sets the severity of each message in the message list to Informational.

warnings

Sets the severity of each message in the message list to Warning.

restore

Restores the saved state of enabling or disabling compiler messages.

save

Saves the current state of enabling or disabling compiler messages.

The `save` and `restore` options are useful primarily within header files. See Section 2.1.1.5.

`#pragma message` performs macro expansion so that you map Version 5.6 message tags to Version 6.0 tags:

HP C++ Implementation

2.1 Implementation-Specific Attributes

```
...
#if __DECCXX_VER > 60000000
#define uninit used_before_set
#endif

#pragma message disable uninit
int main()
{
    int i,j;

    i=j;
}
#pragma message enable uninit
```

2.1.1.12 #pragma module Directive

When you compile source files to create an object file, the compiler assigns the first of the file names specified in the compilation unit to the name of the object file. The compiler adds the .OBJ file extension to the object file. Internally, the OpenVMS system (the debugger and the librarian) recognizes the object module by the file name; the compiler also gives the module a version number of 1. For example, given the object file EXAMPLE.OBJ, the debugger recognizes the EXAMPLE object module.

To change the system-recognized module name and version number, use the #pragma module directive.

You can find the module name and the module version number listed in the compiler listing file and the linker load map.

The #pragma module directive is equivalent to the VAX C compatible #module directive.

The #pragma module directive has the following syntax:

```
#pragma module identifier identifier
#pragma module identifier string
```

The first parameter must be a valid identifier, which specifies the name of the module to be used by the linker. The second parameter specifies the optional identification that appears on the listing and in the object file. The second parameter must be a valid identifier of no more than 31 characters, or a character-string constant of no more than 31 characters.

HP C++ Implementation

2.1 Implementation-Specific Attributes

2.1.1.13 #pragma once Directive

The `#pragma once` preprocessor directive specifies that the header file is evaluated only once.

The `#pragma once` directive has the following format:

```
#pragma once
```

2.1.1.14 #pragma pack Directive

The `#pragma pack` directive specifies the byte boundary for packing member's structures.

The `#pragma pack` directive has the following format:

```
#pragma pack [(n)]  
#pragma pack(push {, identifier} {, n})  
#pragma pack(pop {, identifier} {, n})
```

n specifies the new alignment restriction in bytes as follows:

- | | |
|----|-------------------|
| 1 | Align to byte |
| 2 | Align to word |
| 4 | Align to longword |
| 8 | Align to quadword |
| 16 | Align to octaword |

A structure member is aligned to either the alignment specified by `#pragma pack` or the alignment determined by the size of the structure member, whichever is smaller. For example, a short variable in a structure gets byte-aligned if `#pragma pack (1)` is specified. If `#pragma pack (2)`, `(4)`, or `(8)` is specified, the short variable in the structure gets aligned to word.

If `#pragma pack` is not used, or if *n* is omitted, packing defaults to 1 for byte alignment.

With the push/pop syntax of this pragma, you can save and restore packing alignment values across program components. This allows you to combine components into a single translation unit even if they specify different packing alignments:

- Every occurrence of `pragma pack` with a push argument stores the current packing alignment value on an internal compiler stack. If you provide a value for *n*, that value becomes the new packing value. If you specify an *identifier*, a name of your choosing, it is associated with the new packing value.

HP C++ Implementation

2.1 Implementation-Specific Attributes

- Every occurrence of a `pragma pack` with a `pop` argument retrieves the value at the top of the stack and makes that value the new packing alignment. If an empty stack is popped, the alignment value defaults to the `/[NO]MEMBER_ALIGNMENT` command-line setting, and a warning is issued. If you specify a value for *n*, that value becomes the new packing value.

If you specify an *identifier*, all values stored on the stack are removed from the stack until a matching *identifier* is found. The packing value associated with the *identifier* is also removed from the stack, and the packing value that was in effect just before the *identifier* was pushed becomes the new packing value. If no matching *identifier* is found, the packing value reverts to the command-line setting, and a warning is issued.

The push/pop syntax of `pragma pack` lets you write header files that ensure that packing values are the same before and after the header file is encountered. Consider the following example:

```
// File name: myinclude.h
//
#pragma pack( push, enter_myinclude )
// Your include-file code ...
#pragma pack( pop, enter_myinclude )
// End of myinclude.h
```

In this example, the current packing value is associated with the identifier `enter_myinclude` and pushed on entry to the header file. Your include code is processed. The `#pragma pack` at the end of the header file then removes all intervening packing values that might have occurred in the header file, as well as the packing value associated with `enter_myinclude`, thereby preserving the same packing value after the header file as before it.

This syntax also lets you include header files that might set packing alignments different from the ones set in your code. Consider the following example:

```
#pragma pack( push, before_myinclude )
#include <myinclude.h>
#pragma pack( pop, before_myinclude )
```

In this example, your code is protected from any changes to the packing value that might occur in `<myinclude.h>` by saving the current packing alignment value, processing the include file (which may leave the packing alignment with an unknown setting), and restoring the original packing value.

HP C++ Implementation

2.1 Implementation-Specific Attributes

2.1.1.15 #pragma [no]standard Directive

This directive performs operations similar to the save and restore options on #pragma message directive:

- #pragma standard is the same as #pragma message restore.
- #pragma nostandard disables all optional messages after doing a #pragma message save operation.

2.1.2 Predefined Macros and Names

The compiler defines the following predefined macros and predefined names. For information on using predefined macros in header files in the common language environment, see Section 3.2.

Table 2–2 Predefined Macros

Macro	Description
<code>_BOOL_EXISTS</code>	Indicates that <code>bool</code> is a type or keyword
<code>__BOOL_IS_A_RESERVED_WORD</code>	Indicates that <code>bool</code> is a keyword
<code>__DATE__¹</code>	A string literal containing the date of the translation in the form <code>Mmm dd yyyy</code> , or <code>Mmm d yyyy</code> if the value of the date is less than 10
<code>__FILE__¹</code>	A string literal containing the name of the source file being compiled
<code>__IEEE_FLOAT</code>	Identifies floating-point format for compiling the program. The default value is 1 for OpenVMS I64 systems, and 0 for OpenVMS Alpha and VAX systems.
<code>__LINE__¹</code>	A decimal constant containing the current line number in the C++ source file
<code>__PRAGMA_ENVIRONMENT</code>	Indicates that the <code>pragma environment</code> directive is supported.
<code>__TIME__¹</code>	A string literal containing the time of the translation in the form of <code>hh:mm:ss</code>
<code>_WCHAR_T</code>	Indicates that <code>wchar_t</code> is a keyword

¹Cannot be redefined or undefined

Table 2–3 lists names with a defined value of 1.

HP C++ Implementation

2.1 Implementation-Specific Attributes

Table 2–3 Names with a Defined Value of 1

Name	Description
<code>__cplusplus</code> ¹	Language identification name.
<code>__DECCXX</code>	Language identification name.
<code>__VMS</code>	System identification
<code>__vms</code>	System identification

¹Cannot be redefined or undefined

The compiler predefines `__VMS`; the C compiler predefines `VMS` and `__VMS`. Therefore, C++ programmers who plan to reuse code should check for `__VMS`.

On OpenVMS Alpha systems, the compiler supports the following predefined macro names.

Table 2–4 Predefined Macros Specific to OpenVMS Alpha Systems

Name	Description
<code>__Alpha_AXP</code>	System identification name
<code>__ALPHA</code>	System identification name
<code>__alpha</code>	System identification name
<code>__32BITS</code>	Defined when pointers and data of type <code>long</code> are 32 bits on Alpha platforms

The compiler predefines `__32BITS` when pointers and data of type `long` are 32 bits on Alpha platforms.

On both UNIX and OpenVMS operating systems, programmers should use the predefined macro `__alpha` for code that is intended to be portable from one system to the other.

On OpenVMS I64 systems, the compiler supports the following predefined macro names:

HP C++ Implementation

2.1 Implementation-Specific Attributes

Table 2–5 Predefined Macros Specific to OpenVMS I64 Systems

Name	Description
<code>__ia64</code>	System identification name
<code>__ia64__</code>	System identification name
<code>__32BITS</code>	Defined when pointers and data of type long are 32 bits.

Predefined macros (with the exception of `vms_version`, `VMS_VERSION`, `__vms_version`, `__VMS_VERSION`, and `__INITIAL_POINTER_SIZE`) are defined as 1 or 0, depending on the system (VAX or Alpha processor), the compiler defaults, and the qualifiers used. For example, if you compiled using `G_FLOAT` format, `__D_FLOAT` and `__IEEE_FLOAT` (Alpha processors only) are predefined to be 0, and `__G_FLOAT` is predefined as if the following were included before every compilation unit:

```
#define __G_FLOAT 1
```

These macros can assist in writing code that executes conditionally. They can be used in `#elif`, `#if`, `#ifdef`, and `#ifndef` directives to separate portable and nonportable code in a C++ program. The `vms_version`, `VMS_VERSION`, `__vms_version`, and `__VMS_VERSION` macros are defined with the value of the OpenVMS version on which you are running (for example, Version 6.0).

C++ automatically defines the following macros pertaining to the format of floating-point variables. You can use them to identify the format with which you are compiling your program.

```
__D_FLOAT  
__G_FLOAT  
__IEEE_FLOAT  
__IEEE_FP  
__X_FLOAT
```

The value of `__X_FLOAT` can be 0 or 1 depending on the floating point mode in effect. You can use the `/FLOAT` qualifier to change the mode.

Table 2–6 lists predefined version string and version number macros.

HP C++ Implementation 2.1 Implementation-Specific Attributes

Table 2–6 Version String and Version Number Macros

Name	Description
<code>__VMS_VERSION</code> ¹	Version identification
<code>__vms_version</code> ¹	Version identification
<code>__DECCXX_VER</code> ²	Version identification
<code>__VMS_VER</code> ²	Version identification

¹The value is a character string.

²The value is an unsigned long int that encodes the version number.

For example, the defined value of `__VMS_VERSION` on OpenVMS Version 6.1 is character string `V6.1`.

You can use `__DECCXX_VER` to test that the current compiler version is newer than a particular version and `__VMS_VER` to test that the current OpenVMS Version is newer than a particular version. Newer versions of the compiler and the OpenVMS operating system always have larger values for these macros. If for any reason the version cannot be analyzed by the compiler, then the corresponding predefined macro is defined but has the value of 0. Releases of the compiler prior to Version 5.0 do not define these macros, so you can distinguish earlier compiler versions by checking to determine if the `__DECCXX_VER` macro is defined.

The following example tests for C++ 5.1 or higher:

```
#ifdef __DECCXX_VER
    #if __DECCXX_VER >= 50100000
        /* Code */
    #endif
#endif
```

The following tests for OpenVMS Version 6.2 or higher:

```
#ifdef __VMS_VER
    #if __VMS_VER >= 60200000
        /* code */
    #endif
#endif
```

HP C++ Implementation

2.1 Implementation-Specific Attributes

Table 2–7 shows the macro names for the listed command-line options.

Table 2–7 Macros Defined by Command-Line Qualifiers

Command-line Option	Macro Name
/ALTERNATIVE_TOKENS	__ALTERNATIVE_TOKENS
/ASSUME=GLOBAL_ARRAY_NEW	__GLOBAL_ARRAY_NEW
/ASSUME=STDNEW	__STDNEW
/DEFINE=__FORCE_INSTANTATIONS (Alpha only)	__FORCE_INSTANTIATIONS
/EXCEPTIONS	__EXCEPTIONS
/IEEE_MODE	__IEEE_FP
/IMPLICIT_INCLUDE	__IMPLICIT_INCLUDE_ENABLED
/L_DOUBLE_SIZE	__X_FLOAT
/MODEL=ANSI	__MODEL_ANSI
/MODEL=ARM (Alpha only)	__MODEL_ARM
/PURE_CNAME	__PURE_CNAME, __HIDE_FORBIDDEN_NAMES ¹
/ROUNDING_MODE	__BIASED_FLT_ROUNDS
/RTTI	__RTTI
/STANDARD=RELAXED	__STD_ANSI, __NOUSE_STD_Iostream
/STANDARD=ANSI	__STD_ANSI, __NOUSE_STD_Iostream
/STANDARD=ARM	__STD_ARM, __NOUSE_STD_Iostream
/STANDARD=CFRONT	As of C++ Version 7.1, the CFRONT option is no longer supported.
/STANDARD=GNU	__STD_GNU, __NOUSE_STD_Iostream
/STANDARD=MS	__STD_MS, __NOUSE_STD_Iostream
/STANDARD=STRICT_ANSI	__STD_STRICT_ANSI, __USE_STD_Iostream, __PURE_CNAME, __HIDE_FORBIDDEN_NAMES
/STANDARD=STRICT_ANSI /WARNINGS=ANSI_ERRORS	__STD_STRICT_ANSI_ERRORS, __PURE_CNAME, __HIDE_FORBIDDEN_NAMES

¹When you compile with HP C using any values of /STANDARD that set strict C standard conformance (ANSI89, MIA, C99, and LATEST), versions of the standard header files are included that hide many identifiers that do not follow the rules. The header file <stdio.h>, for example, hides the definition of the macro TRUE. The compiler accomplishes this by predefining the macro __HIDE_FORBIDDEN_NAMES for the above-mentioned /STANDARD values.

You can use the /UNDEFINE="__HIDE_FORBIDDEN_NAMES" command-line qualifier to prevent the compiler from predefining this macro and, thereby, including macro definitions of the forbidden names.

(continued on next page)

HP C++ Implementation

2.1 Implementation-Specific Attributes

Table 2–7 (Cont.) Macros Defined by Command-Line Qualifiers

Command-line Option	Macro Name
/USING=STD	__IMPLICIT_USING_STD
/STANDARD=LATEST	__STD_STRICT_ANSI, __USE_STD_Iostream, __PURE_CNAME, __HIDE_FORBIDDEN_NAMES
/STANDARD=LATEST /WARNINGS=ANSI_ERRORS	__STD_STRICT_ANSI_ERRORS, __PURE_CNAME, __HIDE_FORBIDDEN_NAMES

2.1.3 Translation Limits

The only translation limits imposed in the compiler are as follows:

Limit	Meaning
32,767	Bytes in the representation of a string literal. This limit does not apply to string literals formed by concatenation.
8192	Characters in an internal identifier or macro name.
8192	Characters in a logical name.
8192	Characters in a physical source line, on OpenVMS Alpha systems.
1012	Bytes in any one function argument.
512	Characters in a physical source line, on OpenVMS VAX systems.
255	Arguments in a function call. ¹
255	Parameters in a function definition. ¹
127	Characters in a qualified identifier in the debugger.
31	Significant characters in an external identifier with “C” linkage. A warning is issued if such an identifier is truncated.

¹The compiler may add one or two hidden arguments to a function, which reduces to 254 or 253 the number of arguments available to the user.

2.1.4 Numerical Limits

The numerical limits, as defined in the header files <limits.h> and <float.h> are as follows:

- The number of bits in a character of the execution character set is eight.
- The representation and set of values for type char and for type signed char are the same. You can change this equivalence from signed char to unsigned char with a command-line option.
- The representation and set of values for the short type is 16 bits.

HP C++ Implementation

2.1 Implementation-Specific Attributes

- The representation and set of values for the types `int`, `signed int`, and `long` are the same (32 bits).
- The representation and set of values for type `unsigned int` and for type `unsigned long` are the same (32 bits).
- The representation and set of values for type `double` are 64 bits.
- The representation and set of values for type `long double` are 128 bits unless the `/L_DOUBLE_SIZE=64` qualifier is specified.

Specifying a different `l_double_size` than the default size for your particular version of the operating system does not work correctly with the standard library.

Numerical limits not described in this list are defined in *The Annotated C++ Reference Manual*.

2.1.5 Argument-Passing and Return Mechanisms

The compiler passes arrays, functions, and class objects with a constructor or destructor by reference. All other objects are passed by value.

If a class has a constructor or a destructor, it is not passed by value. In this case, the compiler calls a copy constructor to copy the object to a temporary location, and passes the address of that location to the called function.

If the return value of a function is a class that has defined a constructor or destructor or is greater than 64 bits, storage is allocated by the caller and the address to this storage is passed in the first parameter to the called function. The called function uses the storage provided to construct the return value.

2.2 Implementation Extensions and Features

This section describes the extensions and implementation-specific features of the compiler on OpenVMS systems.

2.2.1 Identifiers

In the compiler, the dollar sign (\$) is a valid character in an identifier.

For each external function with C++ linkage, the compiler decorates the function name with a representation of the function's type.

HP C++ Implementation 2.2 Implementation Extensions and Features

2.2.1.1 External Name Encoding

The compiler uses the external name encoding scheme described in §7.2.1c of *The Annotated C++ Reference Manual*.

For the basic types, the external name encoding scheme is exactly the same as that described in *The Annotated C++ Reference Manual*, as follows:

Type	Encoding
void	v
char	c
short	s
int	i
long	l
float	f
double	d
long double	r
...	e
bool	jb
wchar_t	jw

Class names are encoded as described in *The Annotated C++ Reference Manual*, except that the DEC C++ compiler uses the lowercase `q` instead of uppercase `Q`, and denotes the qualifier count as a decimal number followed by an underscore, as follows:

Class	Notation	Encoding
simple	Complex	7Complex
qualified	X::YY	q2_1x2yy

Type modifiers are encoded as follows:

Modifier	Encoding
const	k
signed	g
volatile	w

HP C++ Implementation

2.2 Implementation Extensions and Features

Modifier	Encoding
unsigned	u
__unaligned	b

Type declarators are encoded as follows:

Type	Notation	Encoding
array	[10]	a10_
function	()	x
pointer	*	p
pointer to member	S::*	m1S
reference	&	n
unnamed enumeration type		h

On OpenVMS Alpha systems, the compiler also supports the following data types:

Type	Encoding
__int16	ji4
__int32	ji5
__int64	ji6
__f_float	jf
__g_float	yg
__s_float	js
__t_float	jt

2.2.1.2 Modifying Long Names

On OpenVMS systems, if an identifier for a function name with C++ linkage exceeds 31 characters, the name is modified as follows:

1. A unique value is generated by hashing the full decorated name. This seven-character code is appended to the end of the name.
2. The name is preceded by the `cxx$` facility prefix.

HP C++ Implementation

2.2 Implementation Extensions and Features

3. The name is truncated in three back-to-front passes, eliminating underscores, then vowels, and then consonants (y is a consonant). A vowel is never removed if the following conditions apply:
 - It occurs as the first character in the fully decorated name.
 - The character before the vowel is either another vowel or is non-alphanumeric.

The hash code added at the end of the name is not truncated.

Truncation ceases when the truncated name, combined with the `cxx$` facility prefix and the unique radix 32 value at the end, equals 31 characters.

For information on how to view the demangled form of these names, see Section 1.6.

2.2.2 Order of Static Object Initialization

Nonlocal static objects are initialized in declaration order within a compilation unit and in link order across compilation units. On OpenVMS systems, the compiler uses the `lib$initialize` mechanism to initialize nonlocal static objects.

2.2.3 Integral Conversions

When demoting an integer to a signed integer, if the value is too large to be represented the result is truncated and the high-order bits are discarded.

Conversions between signed and unsigned integers of the same size involve no representation change.

2.2.4 Floating-Point Conversions

When converting an integer to a floating-point number that cannot exactly represent the original value, the compiler rounds off the result of the conversion to the nearest value that can be represented exactly.

When the result of converting a floating-point number to an integer or other floating-point number at compile time cannot be represented, the compiler issues a diagnostic message.

When converting an integral number or a double floating-point number to a floating-point number that cannot exactly represent the original value, rounds off the result to the nearest value of type `float`.

When demoting a double value to `float`, if the converted value is within range but cannot exactly represent the original value, the compiler rounds off the result to the nearest representable `float` value.

HP C++ Implementation

2.2 Implementation Extensions and Features

the compiler performs similar rounding for demotions from long double to double or float.

2.2.5 Explicit Type Conversion

In C++, the expression `T()` (where `T` is a simple type specifier) creates an rvalue of the specified type, whose value is determined by default initialization. According to the *The C++ Programming Language, 3rd Edition*, the behavior is undefined if the type is not a class with a constructor, but the ANSI/ISO International Standard removes this restriction. With this change you can now write:

```
int i=int(); // i must be initialized to 0
```

2.2.6 The sizeof Operator

The type of the `sizeof` operator is `size_t`. In the header file, `stddef.h`, the compiler defines this type as `unsigned int`, which is the type of the integer that holds the maximum size of an array.

2.2.7 Explicit Type Conversion

A pointer takes up the same amount of memory storage as objects of type `int` or `long` (or their unsigned equivalents). Therefore, a pointer can convert to any of these types and back again without changing its value. No scaling occurs and the representation of the value is unchanged.

Conversions to and from a shorter integer and a pointer are similar to conversions to and from a shorter integer and unsigned `long`. If the shorter integer type was signed, conversion fills the high-order bits of the pointer with copies of the sign bit.

2.2.8 Multiplicative Operators

The semantics of the division (`/`) and remainder (`%`) operator are as follows:

- If either operand of the division operator is negative, the compiler truncates the result toward 0 (that is, the smallest integer larger than the algebraic quotient).
- If either operand of the remainder operator is negative, the result takes the same sign as that of the first operand.

In the following cases of undefined behavior detected at compile time, the compiler issues a warning:

```
Integer overflow  
Division by 0  
Remainder by 0
```

HP C++ Implementation 2.2 Implementation Extensions and Features

2.2.9 Additive Operators (§r.5.7)

You can subtract pointers to members of the same array. The result is the number of elements between the two array members, and is of type `ptrdiff_t`. In the header file `stddef.h`, the compiler defines this type as `int`.

2.2.10 Shift Operators (§r.5.8)

The expression `E1 >> E2` shifts `E1` to the right `E2` positions. If `E1` has a signed type, the compiler fills the vacated high-order bits of the shifted value `E1` with a copy of `E1`'s sign bit (arithmetic shift).

2.2.11 Equality Operators

When comparing two pointers to members, the compiler guarantees equality if either of the following conditions hold:

- Both pointers are `NULL`.
- The same address expression (`&`) created both pointers.

When comparing two pointers to members, the compiler guarantees inequality if either of the following conditions hold:

- Only one pointer is `NULL`.
- Each pointer produces a different member if applied to the same object.

When created by different address expressions, two pointers to members may compare either as equal or as unequal if they produce the same member when applied to the same object.

2.2.12 Type Specifiers

For variables that are modifiable in ways unknown to the compiler, use the `volatile` type specifier. Declaring an object to be `volatile` means that every reference to the object in the source code results in a reference to memory in the object code.

2.2.13 `asm` Declarations *(Alpha only)*

In the compiler, `asm` declarations produce a compile-time error. As an alternative to `asm`, you can use built-in functions. See Appendix C for more information.

HP C++ Implementation

2.2 Implementation Extensions and Features

2.2.14 Linkage Specifications

Specifying linkage other than “C++” or “C” generates a compile-time error.

In object files, the compiler decorates with type information the names of functions with C++ linkage. This permits overloading and provides rudimentary type checking across compilation units. The type-encoding algorithm used is similar to that given in §7.2.1c of *The Annotated C++ Reference Manual* (see Section 2.2.1.1).

2.2.15 Class Layout

The alignment requirements and sizes of structure components affect the structure’s alignment and size. A structure can begin on any byte boundary and occupy any integral number of bytes.

2.2.15.1 Structure Alignment

Structure alignment is controlled by the `/MEMBER_ALIGNMENT` command-line qualifier or by using the `#pragma member_alignment` preprocessor directive. If `/MEMBER_ALIGNMENT` is specified, or implied by default, the maximum alignment required by any member within the structure determines the structure’s alignment. When the structure or union is a member of an array, padding is added to ensure that the size of a record, in bytes, is a multiple of its alignment.

Components of a structure are laid out in memory in the order in which they are declared. The first component has the same address as the entire structure. Padding is inserted between components to satisfy alignment requirements of individual components.

If `/NOMEMBER_ALIGNMENT` is specified, each member of a structure appears at the next byte boundary.

2.2.15.2 Bit-Fields

If `/MEMBER_ALIGNMENT` is specified, or implied by default, the presence of bit-fields causes the alignment of the whole structure or union to be at least the same as that of the bit-field’s base type.

For bit-fields (including zero-length bit-fields) not immediately declared following other bit-fields, their base type imposes the alignment requirements (less than that of type `int`). Within the alignment unit (of the same size as the bit-field’s base type), bit-fields are allocated from low order to high order. If a bit-field immediately follows another bit-field, the bits are packed into adjacent space in the same unit, if sufficient space remains; otherwise, padding is inserted at the end of the first bit-field and the second bit-field is put into the next unit.

HP C++ Implementation

2.2 Implementation Extensions and Features

Bit-fields of base type `char` must be smaller than 8 bits. Bit-fields of base type `short` must be smaller than 16 bits.

2.2.15.3 Access Specifiers

The layout of a class is unaffected by the presence of access specifiers.

2.2.15.4 Class Subobject Offsets

A class object that has one or more base classes contains instances of its base classes as subobjects. The offsets of nonvirtual base class subobjects are less than the offsets of any data members that are not part of base class subobjects.

The offsets of nonvirtual base classes increase in derivation order. The offset of the first nonvirtual base class subobject of any class is 0. For single inheritance, the address of a class object is always the same as the address of its base class subobject.

If a class has virtual functions, an object of that class contains a pointer to a virtual function table (VFPTR).

If a class has virtual base classes, an object of that class contains a pointer to a virtual base class table (VBPTR).

For a class with no base classes, the offset of a VFPTR or VBPTR is greater than the offset of any data members. Thus, the offset of the first data member of a class with no base classes is 0, which facilitates interoperability with other languages. If the leftmost base class of a subclass has a VFPTR, a VBPTR, or both, and is not virtual, the class and its base class share the table or tables.

The offsets of virtual base class subobjects are greater than the offset of any data member, and increase in the order of derivation of the virtual base classes. In increasing order, a class object contains the following:

1. Nonvirtual base class subobjects
2. Data members
3. VFPTR (if required)
4. VBPTR (if required)
5. Virtual base class subobjects

Consider the following example:

HP C++ Implementation

2.2 Implementation Extensions and Features

```
class B1
{
    int x[1];
};
class B2 : virtual B1
{
    int y[2];
    virtual int f1();
};
class B3 : virtual B2, virtual B1
{
    int z[3];
    virtual int f2();
};
class D : B3
{
    int a[4];
    virtual int f1(), f2(), f3();
};
```

Figure 2–1 shows the layout of an object of D class for this example.

2.2.16 Virtual Function and Base Class Tables

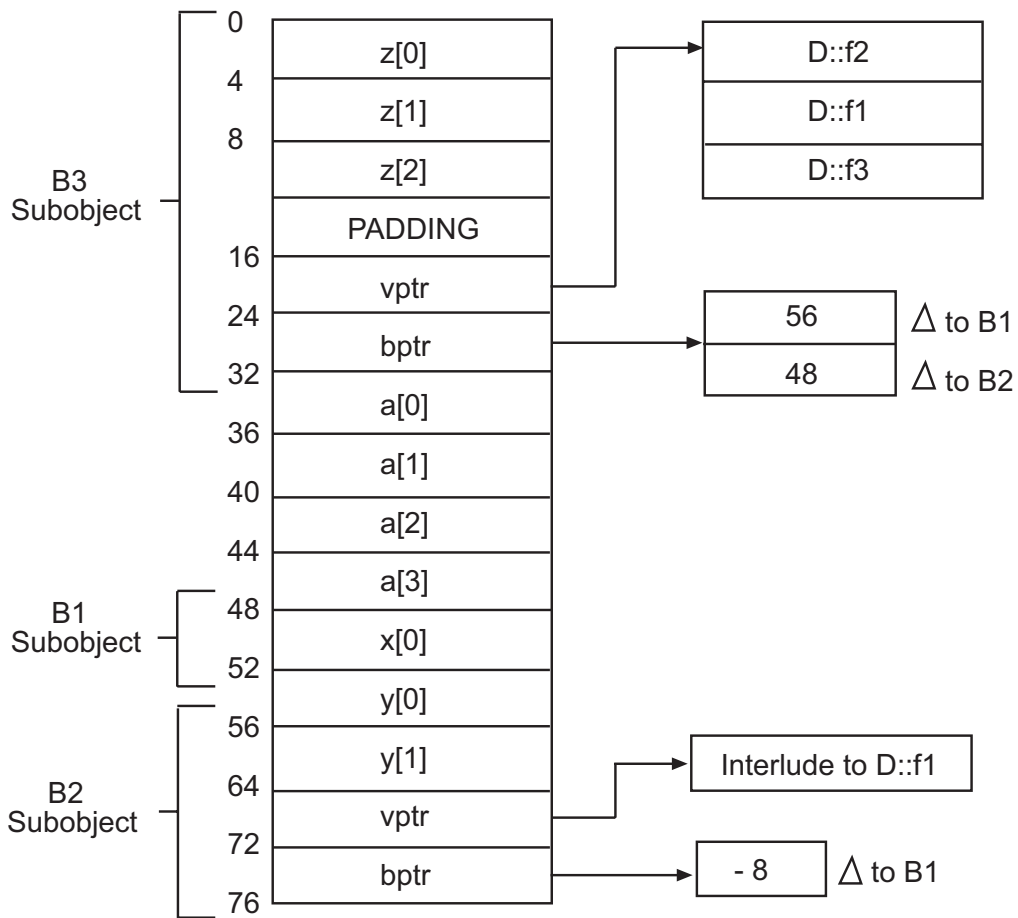

The compiler allocates storage for virtual function tables (VTBLs) and base class tables (BTBLs) using the common block extern model. All references to VTBLs and BTBLs share a single copy. (The compiler specifies the local (LCL) PSECT attribute for these tables. Thus, one copy of each table exists for each program image file.) This means that you need not be concerned with the associations of these tables during compilation, and the compiler command switch `+e` supplied in other implementations is not needed for HP C++ for OpenVMS systems.

2.2.17 Multiple Base Classes

Within a class object, base class subobjects are allocated in derivation order; that is, immediate base classes are allocated in the order in which they appear in the class declaration.

HP C++ Implementation
2.2 Implementation Extensions and Features

Figure 2–1 Layout of an Object of D Class

2.2.18 Temporary Objects

Under the following conditions, the compiler creates temporary objects for class objects with constructors:

- An object is returned from a function.
- An object is passed as an argument.
- An object is created using the constructor notation.

HP C++ Implementation

2.2 Implementation Extensions and Features

- A user-defined conversion is implicitly used.

Variations in the compiler generation of such temporary objects can adversely affect their reliability in user programs. The compiler avoids introducing a temporary object whenever it discovers that the temporary object is not needed for accurate compilation. Therefore, you should modify or write your programs so as not to depend on side effects in the constructors or destructors of temporary objects.

2.2.18.1 Lifetime of Temporary Objects

Generally the compiler implements destruction of temporary objects at the end of statements. In certain situations, however, temporary objects are destroyed at the end of the expression; they do not persist to the end of the statement. Temporary objects do not persist to the end of statements in expressions that are:

- In operands of built-in conditional operators (`||` and `&&`)
- In the second or third operand of the ternary operator (`?:`)
- Operands to the built-in comma operator (`,`)

Consider the following example:

```
struct A {
    void print(int i);
    A();
    ~A() { }
};

struct B {
    A* find(int i);
    B(int i);
    B();
    ~B() { }
};

void f() {
    B(8).find(6)->print(6);
    (*(B(5).find(3))).print(3);
    return;
}
```

In the first and second statements inside `void f()`, the compiler destroys the temporary object created in evaluating the expressions `B(8)` and `B(5)` after the call to `A::print(int)`.

HP C++ Implementation 2.2 Implementation Extensions and Features

2.2.18.2 Nonconstant Reference Initialization with a Temporary Object

If your program tries to initialize a nonconstant reference with a temporary object, the compiler generates a warning. For example:

```
struct A {
    A(int);
};
void f(A& ar);

void g() {
    f(5); // warning!!
}
```

2.2.18.3 Static Member Functions Selected by Expressions Creating Temporary Objects

When a static member is accessed through a member access operator, the expression on the left side of the dot (.) or right arrow (->) is not evaluated. In such cases, the compiler creates code that calls the static member function to handle the destruction of a class type temporary; the compiler does not create temporary destructor code. For example:

```
struct A {
    ~A();
    static void sf();
};

struct B {
    A operator ()() const;
};

void f () {
    B bobj;
    bobj().sf(); // If 'bobj()' is evaluated, a temporary of
                // type 'A' is created.
}
```

2.2.19 File Inclusion

The #include directive inserts external text into the macro stream delivered to the compiler. Programmers often use this directive to include global definitions for use with compiler functions and macros in the program stream.

On OpenVMS systems, the #include directive may be nested to a depth determined by the FILLM process quota and by virtual memory restrictions. The compiler imposes no inherent limitation on the nesting level of inclusion.

HP C++ Implementation

2.2 Implementation Extensions and Features

In C++ source programs, inclusion of both OpenVMS and most UNIX style file specifications is valid. For example, the following is a valid UNIX style file specification:

```
nodename!/device/directory/filename.dat.3
```

The exclamation point (!) separates the node name from the rest of the specification; slash characters (/) separate devices and directories; periods (.) separate file types and file versions. Because one character separates two segments of the file specification, ambiguity can occur.

The `/INCLUDE_DIRECTORY=(pathname,...)` qualifier provides an additional level of search for user-defined include files. Each *pathname* argument can be either a logical name or a legal UNIX style directory in a quoted string. The default is `/NOINCLUDE_DIRECTORY`.

The qualifier provides functionality similar to the `-I` option of the `cxx` command on Tru64 UNIX systems. This qualifier allows you to specify additional locations to search for files to include. Putting an empty string in the specification prevents the compiler from searching any of the locations it normally searches but directs it to search *only* in locations you identify explicitly on the command line with the `/INCLUDE_DIRECTORY` and `/LIBRARY` qualifiers (or by way of the specification of the primary source file, depending on the `/NESTED_INCLUDE_DIRECTORY` qualifier).

The basic order for searching depends on the form of the header name (after macro expansion), with additional aspects controlled by other command line qualifiers as well as the presence or absence of logical name definitions. The valid possibilities for names are as follows:

- Enclosed in quotes. For example: "stdio.h"
- Enclosed in angle brackets. For example: <stdio.h>

Unless otherwise defined, searching a location means that the compiler uses the string specifying the location as the default file specification in a call to an RMS system service (that is, a `$SEARCH/$PARSE`) with a primary file specification consisting of the name in the `#include` (without enclosing delimiters). The search terminates successfully as soon as a file can be opened for reading.

Specifying a null string in the `/INCLUDE` qualifier causes the compiler to do a non-standard search. This search path is as follows:

1. The current directory (quoted form only)
2. Any directories specified in the `/INCLUDE` qualifier
3. The directory of the primary input file

HP C++ Implementation 2.2 Implementation Extensions and Features

4. Text libraries specified on the command line using `/LIBRARY`

For standard searches, the search order is as follows:

1. Search the current directory (directory of the source being processed).
If angle-bracket form, search only if no directories are specified with `/INCLUDE_DIRECTORY`.
2. Search the locations specified in the `/INCLUDE_DIRECTORY` qualifier (if any).
3. If `CXX$SYSTEM_INCLUDE` is defined as a logical name, search `CXX$SYSTEM_INCLUDE:.HXX` or just `CXX$SYSTEM_INCLUDE:.`, depending on the qualifier `/ASSUME=NOHEADER_TYPE_DEFAULT`. If nothing is found, go to step 6.
4. If `CXX$LIBRARY_INCLUDE` is defined as a logical name, `CXX$LIBRARY_INCLUDE:.HXX` or `CXX$LIBRARY_INCLUDE:.`, depending on the qualifier `/ASSUME=NOHEADER_TYPE_DEFAULT`. If nothing is found, go to step 6.
5. If `/ASSUME=HEADER_TYPE_DEFAULT` is not specified, search the default list of locations for plain-text copies of compiler header files as follows:

```
SYS$COMMON:[CXX$LIB.INCLUDE.CXXL$ANSI_DEF]
SYS$COMMON:[CXX$LIB.INCLUDE.DECC$RTLDEF_HXX].HXX
SYS$COMMON:[CXX$LIB.INCLUDE.DECC$RTLDEF].H
SYS$COMMON:[CXX$LIB.INCLUDE.SYS$STARLET_C].H
```

If `/ASSUME=HEADER_TYPE_DEFAULT` is specified, search the default list of locations for plain-text copies of compiler header files as follows:

```
SYS$COMMON:[CXX$LIB.INCLUDE.DECC$RTLDEF_HXX].HXX
SYS$COMMON:[CXX$LIB.INCLUDE.DECC$RTLDEF].H
SYS$COMMON:[CXX$LIB.INCLUDE.SYS$STARLET_C].H
SYS$COMMON:[CXX$LIB.INCLUDE.CXXL$ANSI_DEF]
```

6. Search the directory of the primary input file.
7. If quoted form, and `CXX$USER_INCLUDE` is defined as a logical name, search `CXX$USER_INCLUDE:.HXX` or `CXX$USER_INCLUDE:.`, depending on the `/ASSUME=NOHEADER_TYPE_DEFAULT` qualifier.
8. Search the text libraries. Extract the simple file name and file type from the `#include` specification, and use them to determine a module name for each text library. There are three forms of module names used by the compiler:

1. type stripped:

HP C++ Implementation

2.2 Implementation Extensions and Features

The file type will be removed from the include file specification to form a library module name. Examples:

```
#include "foo.h"           Module name "FOO"  
#include "foo"            Module name "FOO"  
#include "foo"            Module name "FOO"
```

2. type required:

The file type must be a part of the file name. Examples:

```
#include "foo.h"           Module name "FOO.H"  
#include "foo"            Module name "FOO."  
#include "foo"            Module name "FOO."
```

3. type optional:

First an attempt is made to find a module with the type included in the module name. If this is unsuccessful, an attempt is made with the type stripped from the module name. If this is unsuccessful, the search moves on to the next library.

If /ASSUME=HEADER_TYPE_DEFAULT is specified, the following text libraries are searched in this order:

```
Libraries specified on the command line with the /LIBRARY qualifier  
(all files, type stripped)  
CXX$TEXT_LIBRARY (all files, type stripped)  
DECC$RTLDEF (H files and unspecified files, type stripped)  
SYS$STARLET_C (all files, type stripped)  
CXXL$ANSI_DEF (unspecified files, type stripped)
```

Otherwise, these text libraries are searched in this order:

```
Libraries specified on the command line with the /LIBRARY qualifier  
(all files, type optional)  
CXX$TEXT_LIBRARY (all files, type optional)  
CXXL$ANSI_DEF (all files, type required)  
DECC$RTLDEF (H files and unspecified files, type stripped)  
SYS$STARLET_C (all files, type stripped)
```

Two text library search examples (stop when something is found):

HP C++ Implementation 2.2 Implementation Extensions and Features

Example 1

```
#include "foo"
```

1. For each library specified via the /LIBRARY qualifier:
 - Look for "FOO."
 - Look for "FOO"
2. Look for "FOO." in CXX\$TEXT_LIBRARY
3. Look for "FOO" in CXX\$TEXT_LIBRARY
4. Look for "FOO." in CXXL\$ANSI_DEF (Do not look for "FOO" because the type is required as part of the module name)
5. Look for "FOO" in DECC\$RTLDEF (not "FOO." because the type must not be part of the module name)
6. Look for "FOO" in SYS\$STARLET_C (not "FOO." because the type must not be part of the module name)

Example 2

```
#include "foo.h"
```

1. For each library specified via the /LIBRARY qualifier:
 - Look for "FOO.H"
 - Look for "FOO"
2. Look for "FOO.H" in CXX\$TEXT_LIBRARY
3. Look for "FOO" in CXX\$TEXT_LIBRARY
4. Look for "FOO.H" in CXXL\$ANSI_DEF (Do not look for "FOO" because the type is required as part of the module name)
5. Look for "FOO" in DECC\$RTLDEF (not "FOO.H" because the type must not be part of the module name)
6. Look for "FOO" in SYS\$STARLET_C (not "FOO.H" because the type must not be part of the module name)
7. If neither CXX\$LIBRARY_INCLUDE nor CXX\$SYSTEM_INCLUDE is defined as a logical name, then search SYS\$LIBRARY.HXX.

HP C++ Implementation

2.2 Implementation Extensions and Features

2.2.20 Nested Enums and Overloading

The C++ language allows programmers to give distinct functions the same name, and uses either overloading or class scope to differentiate the functions:

```
void f(int);
void f(int *);
class C {void f(int);};
class D {void f(int);};
```

Yet, linkers cannot interpret overloaded parameter types or classes, and they issue error messages if they find more than one definition of any external symbol. C++ compilers, including HP C++, solve this problem by assigning a unique **mangled name** (also called **type safe linkage name**) to every function. These unique mangled names allow the linker to tell the overloaded functions apart.

The compiler forms a mangled name, in part, by appending an encoding of the parameter types of the function to the function's name, and if the function is a member function, the function name is qualified by the names of the classes within which it is nested.

For example, for the function declarations at the beginning of this section, the compiler might generate the mangled names `f__Xi`, `f__XPi`, `f__1CXi`, and `f__1DXi` respectively. In these names, `i` means a parameter type was `int`, `P` means "pointer to", `1C` means nested within class `C`, and `1D` means nested within class `D`.

There is a flaw in the name mangling scheme used by the compiler that can cause problems in uncommon cases. The compiler fails to note in the encoding of an enum type in a mangled name whether the enum type was nested within a class. This can cause distinct overloaded functions to be assigned the same mangled name:

```
struct C1 {enum E {red, blue};};
struct C2 {enum E {red, blue};};

extern "C" int printf(const char *, ...);
void f(C1::E x) {printf("f(C1::E)\n");}
void f(C2::E x) {printf("f(C2::E)\n");}

int main()
{
    f(C1::red);
    f(C2::red);
    return 1;
}
```

HP C++ Implementation

2.2 Implementation Extensions and Features

In the previous example, the two overloaded functions named `f` differ only in that one takes an argument of enum type `C1::E` and the other takes an argument of enum type `C2::E`. Since the compiler fails to include the names of the classes containing the enum type in the mangled name, both functions have mangled names that indicate the argument type is just `E`. This causes both functions to receive the same mangled name.

In some cases, the compiler detects this problem at compile-time and issues a message that both functions have the same type-safe linkage. In other cases, the compiler issues no message, but the linker complains about duplicate symbol definitions.

If you encounter such problems, you can recompile using the `/DISTINGUISH_NESTED_ENUMS` qualifier (*Alpha only*). This causes the compiler, when forming a mangled name, to include the name of class or classes within which an enum is nested, thereby preventing different functions from receiving the same the same mangled name.

Because the `/DISTINGUISH_NESTED_ENUMS` qualifier changes the external symbols the compiler produces, you can get undefined symbol messages from the linker if some modules are compiled with `/DISTINGUISH_NESTED_ENUMS` and some are compiled without it. Because of this, `/DISTINGUISH_NESTED_ENUMS` might make it difficult to link against old object files or libraries of code.

If you compile your code with `/DISTINGUISH_NESTED_ENUMS` and try to link against a library that was compiled without the `/DISTINGUISH_NESTED_ENUMS` qualifier, you receive an undefined symbol message from the linker if you attempt to call a function from the library that takes an argument of a nested enum type. The mangled name of the function in the library will be different from the mangled name your code is using to call the function.

Note that the `/DISTINGUISH_NESTED_ENUMS` qualifier has no meaning on I64 systems because it modifies the behavior of programs compiled with `/MODEL=ARM`, and that model is not supported on I64 systems.

2.2.21 Guiding Declarations

A guiding declaration is a function declaration that matches a function template, does not introduce a function definition (implies an instantiation of the template body and not a explicit specialization), and is subject to different argument matching rules than those that apply to the template itself—therefore affecting overload resolution. Consider the following example:

HP C++ Implementation

2.2 Implementation Extensions and Features

```
template <class T> void f(T) {
    printf("In template f\n");
}

void f(int);

int main() {
    f(0); // invokes non-template f
    f<>(0.0); // invokes template f
    return 0;
}

void f(int) {
    printf("In non-template f\n");
}
```

Because there is no concept of guiding declaration in the current version of the C++ International Standard, the function `f` in the example is not regarded as an instance of function template `f`. Furthermore, there are two functions named `f` that take an `int` parameter. A call of `f(0)` would invoke the former, while a call of `f<>(0)` would be required to invoke the latter.

2.3 Alternative Tokens

The compiler supports use of alternative tokens:

/[no]alternative_tokens

Enable use of operator keywords and digraphs to generate tokens as follows:

Operator Keyword	Token
<code>and</code>	<code>&&</code>
<code>and_eq</code>	<code>&=</code>
<code>bitand</code>	<code>&</code>
<code>bitor</code>	<code> </code>
<code>compl</code>	<code>~</code>
<code>not</code>	<code>!</code>
<code>not_eq</code>	<code>!=</code>
<code>or</code>	<code> </code>
<code>or_eq</code>	<code> =</code>
<code>xor</code>	<code>^</code>
<code>xor_eq</code>	<code>^=</code>

Digraph	Token
<code>::></code>	<code>]</code>
<code><:</code>	<code>[</code>
<code>%></code>	<code>}</code>
<code><%</code>	<code>{</code>
<code>%;</code>	<code>#</code>

2.4 Run-time Type Identification

The compiler emits type information for **run-time type identification** (RTTI) in the object module with the virtual function table, for classes that have virtual function tables.

You can specify the `/[NO]RTTI` qualifier to enable or disable support for RTTI (runtime type identification) features: `dynamic_cast` and `typeid`. Disabling runtime type identification can also save space in your object file because static information to describe polymorphic C++ types is not generated. The default is to enable runtime type information features and generate static information in the object file.

Specifying `/NORTTI` does not disable exception handling.

The type information for the class may include references to the type information for each base class and information on how to convert to each. The `typeid` references are mangled in the form `__T__<class>`.

2.5 Message Control and Information Options

The compiler supports the following message control options. The options apply only to warning and informational messages. The *ident* variable is obtained from the error message.

Indicated messages can specify one or more message identifiers *ident* or the message group name `all`.

The default qualifier, `/WARNINGS`, outputs all enabled informational and warning messages. The `/NOWARNINGS` qualifier suppresses both the informational and the warning messages.

Message options are processed and take effect in the following order:

HP C++ Implementation

2.5 Message Control and Information Options

/WARNINGS=NOWARNINGS

Disable all warnings.

/WARNINGS=INFORMATIONALS

Enable informationals.

Although `/WARNINGS=INFORMATIONALS` enables most informationals, we recommend using `/WARNINGS=ENABLE=ALL` instead.

/WARNINGS=INFORMATIONALS=ALL or (*ident*,...)

Set the severity of the specified messages to Informational. You can specify ALL, which applies only to discretionary messages. The ALL option also enables informationals that are disabled by default.

With Version 7.1 of the C++ compiler, `/WARNINGS=INFORMATIONALS=<tag>` no longer enables all other informational messages.

/WARNINGS=WARNING=ALL or (*ident*,...)

Set the severity of the specified messages to Warning. You can specify ALL, which applies only to discretionary messages.

/WARNINGS=[NO]ANSI_ERRORS

Issue error messages for all ANSI violations when in STRICT_ANSI mode. The default is `/WARNINGS=NOANSI_ERRORS`.

/WARNINGS=ERRORS=ALL or (*ident*,...)

Set the severity of the specified messages to Error. You can specify ALL, which applies only to discretionary messages.

/WARNINGS=ENABLE=ALL or (*ident*,...)

Enable all compiler messages, including informational-level messages. Enable specific messages that normally would not be issued when using /QUIET. You can also use this option to enable messages disabled with `/WARNINGS=DISABLE`.

/WARNINGS=DISABLE=ALL or (*ident*,...)

Disable message. This can be used for any nonerror message.

/QUIET

Be more like Version 5.n error reporting. Fewer messages are issued using this option.

This is the default in arm mode (`/STANDARD=ARM`). All other modes default to `/NOQUIET`.

HP C++ Implementation 2.5 Message Control and Information Options

You can use the `/WARNINGS=ENABLE` option with this option to enable specific messages normally disabled using `/QUIET`.

The compiler supports the following message information option, which is disabled by default.

`/WARNINGS=[NO]TAGS`

Display a descriptive tag with each message. "D" indicates that the message is discretionary and that its severity can be changed from the command line or with a pragma. The tag displayed can be used as the *ident* variable in the `/WARNINGS` options.

Example:

```
$ cxx/warnings=tags t.cxx
f() {}
^
%CXX-W-NOSIMPINT, omission of explicit type is nonstandard ("int" assumed)
      (D:nosimpint)
at line number 1 in file CXX$:[SMITH]STD.CXX;1

f() {}
^
.....
%CXX-W-MISSINGRETURN, non-void function "f" (declared at line 1) should
      return a value (D:missingreturn)
at line number 1 in file CXX$:[SMITH]STD.CXX;1

$ cxx /warnings=(notags,disable=nosimpint) t.cxx
f() {}
^
.....
%CXX-W-MISSINGRETURN, non-void function "f" (declared at line 1) should
      return a value
at line number 1 in file CXX$:[SMITH]STD.CXX;1
```

Also see the `#pragma` message preprocessor directive.

3

C++ Language Environment

This chapter describes the guidelines and procedures for customizing your language environment. It includes sections on changing your C header files to work with C++, organizing your C++ files, interfacing to other programming languages, and designing upwardly compatible C++ classes.

3.1 `cname` Headers

The C++ compiler implements section 17.4.1.2 - Headers [lib.headers] "C++ Headers for C Library Facilities" of the C++ Standard. See also Stroustrup's *The C++ Programming Language, 3rd Edition* sections 9.2.2 and 16.1.2.

The implementation consists of eighteen `<cname>` headers defined in the C++ Standard:

```
<cassert> <cctype> <cerrno> <cfloat>
<ciso646> <climits> <locale> <cmath>
<csetjmp> <csignal> <cstdlib> <cstdlib>
<cstdio> <stdlib> <cstring> <ctime>
<wchar> <wctype>
```

As required by the C++ Standard, the `<cname>` headers define C names in the `std` namespace. In `/NOPURE_CNAME` mode, the names are also inserted into the global namespace. See the description of the `/[NO]PURE_CNAME` compiler qualifier.

The `<cname>` headers are located in the same TLB library that contains the C++ standard library and class library headers: `SYS$SHARE:CXXL$ANSI_DEF.TLB`.

C++ Language Environment

3.1 cname Headers

Examples

1.

```
#include <cstdio>
void foo() {
    getchar(); // OK in /NOPURE_CNAME mode
              // %CXX-E-UNDECLARED in /PURE_CNAME mode
}
```

2.

```
#include <cstdio>
void foo() {
    std::getchar(); // OK in both modes
}
```

3.

```
#include <stdio.h>
void foo() {
    getchar(); // OK in both modes
    std::getchar(); // OK in both modes
}
```

3.2 Using Existing C Header Files

C header files that already conform to ANSI C standards must be modified slightly to be usable by HP C++ programs. In particular, be sure to address the following issues:

- Enable the proper linkage for each language.
- Ensure that C++ keywords are not used as identifiers.
- Reconcile any namespace and scoping differences.

The compiler provides some C header files that have been modified to work with C++, including standard ANSI C header files. These headers are in the SYS\$LIBRARY directory.

The following sections provide details on how to properly modify your headers.

C++ Language Environment

3.2 Using Existing C Header Files

3.2.1 Providing C and C++ Linkage

To modify header files, use conditional compilation and the extern specifier.

When programming header files to be used for both C and C++ programs, use the following convention for predefined macros. The system header files also provide an example of correct usage of the predefined macros.

```
#if defined __cplusplus
    /* If the functions in this header have C linkage, this
     * will specify linkage for all C++ language compilers.
     */
    extern "C" {
#endif

# if defined __DECC || defined __DECCXX
    /* If you are using pragmas that are defined only
     * with DEC C and DEC C++, this line is necessary
     * for both C and C++ compilers. A common error
     * is to only have #ifdef __DECC, which causes
     * the compiler to skip the conditionalized
     * code.
     */
# pragma __extern_model __save
# pragma __extern_model __strict_refdef
extern const char some_definition [];
# pragma __extern_model __restore
# endif

    /* ...some data and function definitions go here... */

#if defined __cplusplus
    } /* matches the linkage specification at the beginning. */
#endif
```

See §r.7.4 of *The C++ Programming Language, 3rd Edition* for more information on linkage specifications.

3.2.2 Resolving C++ Keyword Conflicts

If your program uses any of the following C++ language keywords as identifiers, you must replace them with nonconflicting identifiers:

asm	bool	catch	class
const_cast	delete	dynamic_cast	explicit
export	false	friend	inline
mutable	namespace	new	operator
private	protected	public	reinterpret_cast
static_cast	template	this	throw
true	try	typeid	typename

C++ Language Environment

3.2 Using Existing C Header Files

```
virtual          wchar_t
```

Alternative representation keywords are as follows:

```
and, and_eq, bitand, bitor, compl, not, not_eq, or, or_eq, xor, xor_eq
```

3.2.3 Handling Scoping Issues

Distinctions between ANSI C and C++ include slight differences in rules concerning scope. Therefore, you may need to modify some ANSI C header files to use them with C++.

The following sample code fragment generates an error regarding incompatible types, but the root cause is the difference in scope rules between C and C++. In ANSI C, the compiler promotes tag names defined in structure or union declarations to the containing block or file scope. This does not happen in C++.

```
struct Screen {
    struct _XDisplay *display;
};
typedef struct _XDisplay {
    // ...
} Display;

struct Screen s1;
Display      *s2;

main()
{
    s1.display = s2;
}
```

The offending line in this sample is `s1.display = s2`. The types of `s1.display` and `s2` are the same in C but different in C++. You can solve the problem by adding the declaration `struct _XDisplay;` to the beginning of this code fragment, as follows:

```
struct _XDisplay; // this is the added line
struct Screen {
    struct _XDisplay *display;
};
typedef struct _XDisplay {
    // ...
} Display;
// ...
```

C++ Language Environment

3.2 Using Existing C Header Files

3.2.4 Support for <stdarg.h> and <varargs.h> Header Files

The C compiler special built-in macros defined in the header files <stdarg.h> and <varargs.h>. These step through the argument list of a routine.

Programs that take the address of a parameter, and use pointer arithmetic to step through the argument list to obtain the value of other parameters, assume that all arguments reside on the stack and that arguments appear in increasing order. These assumptions are not valid for HP C++. The macros in <varargs.h> can be used only by C functions with old-style definitions that are not legal in C++. To reference variable-length argument lists, use the <stdarg.h> header file.

The OpenVMS calling standard mechanism for returning structures larger than 8 bytes by value uses a hidden parameter. The parameter is a pointer to storage in the caller's frame. The `va_count` macro includes this parameter in its count.

3.3 Using HP C++ with Other Languages

The following are suggestions regarding the use of HP C++ with other languages:

- Passing entities, such as classes, by reference is safest.
- You cannot invoke class member functions from within any language other than C++.
- Every C++ routine that will be called from the other language should be declared in C++ with `extern "C"`. For example:

```
extern "C"  
    int myroutine(int, float);
```

The `extern "C"` will cause the routine to have an unmangled name, so that you can refer to it as `myroutine` from a language such as Cobol or Fortran. Otherwise the routine's link name will be mangled into something like `myrout__Xif`.

- If the main routine is defined in the other language, you will probably need to use the other language's command-line interface to perform your link step. To include the appropriate C++ libraries and startup file, you will need to add some arguments to the command line. The most reliable way to determine what is needed is to test with a small C++ program.

C++ Language Environment

3.4 Linkage to Non-C++ Code and Data

3.4 Linkage to Non-C++ Code and Data

With linkage specifications, you can both import code and data written in other languages into a HP C++ program and export HP C++ code and data for use with other languages. See §4.4 of *The C++ Programming Language, 3rd Edition* for details on the extern "C" declaration.

3.5 How to Organize Your C++ Code

This section explains the best way for compiler users to organize an application into files; it assumes that you are using automatic instantiation to instantiate any template classes and functions.

3.5.1 Code That Does Not Use Templates

The general rule is to place *declarations* in *header files* and place *definitions* in *library source files*. The following items belong in header files:

- Class declarations
- Global function declarations
- Global data declarations

And the following items belong in library source files:

- Static member data definitions
- Out-of-line member function definitions
- Out-of-line global function definitions
- Global data definitions

Header files should be directly included by modules that need them. Because several modules may include the same header file, a header file must not contain definitions that would generate multiply defined symbols when all the modules are linked together.

Library source files should be compiled individually and then linked into your application. Because each library source file is compiled only once, the definitions it contains will exist in only one object module and multiply defined symbols are thus avoided.

For example, to create a class called "array" you would create the following two files:

C++ Language Environment

3.5 How to Organize Your C++ Code

Header file, `arrayInt.hxx`:

```
// arrayInt.hxx
#ifndef ARRAY_H
#define ARRAY_H

class arrayInt {
private:
    int curr_size;
    static int max_array_size;
public:
    arrayInt() :curr_size(0) {}
    arrayInt(int);
};

#endif
```

Library source file, `arrayInt.cxx`:

```
// arrayInt.cxx
#include "arrayInt.hxx"

int array::max_array_size = 256;
arrayInt::arrayInt(int size) : curr_size(size) { ...; }
```

You would then compile the `arrayInt.cxx` library source file using the following command:

```
cxx/include=[.include] arrayInt.cxx
```

The resulting object file could either be linked directly into your application or placed in a library (see Section 3.5.4).

The header file uses **header guards**, which is a technique to prevent multiple inclusion of the same header file.

3.5.2 Code That Uses Templates

With the widespread use of templates in C++, determining the proper place to put declarations and definitions becomes more complicated.

The general rule is to place template declarations and definitions in header files, and to place specializations in library source files.

Thus, the following items belong in template declaration files:

- Declarations of global function templates
- Declarations of class templates
- Declarations of global function template specializations
- Declarations of class template specializations

C++ Language Environment

3.5 How to Organize Your C++ Code

The following items can be placed either in the header file with the corresponding template declaration or in a separate header file that can be implicitly included when needed. This file has the same basename as the corresponding declaration header file, with a suffix that is found by implicit inclusion. For example, if the declaration is in the header file `incl.h`, these corresponding definitions could be in file `incl.cxx`.

- Definitions of out-of-line global function templates
- Definitions of static member data of class templates
- Definitions of out-of-line member functions of class templates

The following must be placed in library source files to prevent multiple definition errors:

- Definitions of global function template specializations
- Definitions of static member data specializations of class templates
- Definitions of out-of-line class member function specializations

These guidelines also apply to nontemplate nested classes inside of template classes.

Note

Do not place definitions of nontemplate class members, nontemplate functions, or global data within template definition files; these must be placed in library source files.

All these header files should use header guards, to ensure that they are not included more than once either explicitly or by implicit inclusion.

For example, the array class from Section 3.5.1, modified to use templates, would now look as follows:

Template declaration file, `array.hxx`:

```
// array.hxx
#ifndef ARRAY_HXX
#define ARRAY_HXX
```

C++ Language Environment 3.5 How to Organize Your C++ Code

```
template <class T>
class array {
private:
    int curr_size;
    static int max_array_size;
public:
    array() :curr_size(0) {}
    array(int size,const T& value = T());
};
#endif
```

Template definition file, array.cxx:

```
// array.cxx
template <class T>
int array<T>::max_array_size = 256;

template <class T>
array<T>::array(int size,const T& value ) {... ; }
```

Then you would create a source file `myprog.cxx` that uses the `array` class as follows:

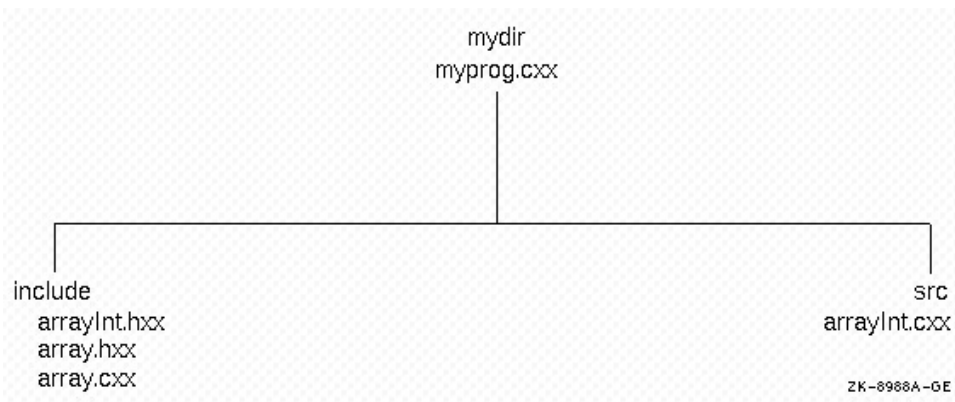

```
// myprog.cxx
#include "array.hxx"
main() {
    array<int> ai;
    // ...
}
```

Figure 3–1 shows the placement of these files.

C++ Language Environment

3.5 How to Organize Your C++ Code

Figure 3–1 Placement of Template Declaration and Definition Files

You would then compile `myprog.cxx` in the `mydir` directory with the following command:

```
cxx/incl=[.include] myprog.cxx
```

In this case, you do not need to create library source files because the static member data and out-of-line members of the `array` template class are instantiated at the time you compile `myprog.cxx`.

However, you would need to create library source files for the following cases:

- Your template declaration file declares nontemplate classes, global functions, or global data that require definitions in a library source file.
- A template class declares an out-of-line nontemplate friend function whose definition must be placed in a library source file.
- Your template declaration file declares a specialization of a template class whose static member data or out-of-line member function definitions must be placed in a library source file.
- Your template declaration file declares an out-of-line specialization of a template function, whose definition must be placed in a library source file.

C++ Language Environment

3.5 How to Organize Your C++ Code

3.5.3 Summary

Table 3–1 describes where to place declarations and definitions, as discussed in Section 3.5.1 and Section 3.5.2.

Table 3–1 Declaring and Defining Classes, Functions, and Data

Feature	Declaration	Out-of-Line Definition
Class	Header file	
Static member data	Within class declaration	Library source file
Member function	Within class declaration	Library source file
Global function	Header file	Library source file
Global data	Header file	Library source file
Template class	Template declaration file	
Static member data of template class	Within template class declaration	Template definition file
Member function of template class	Within template class declaration	Template definition file
Global template function	Template declaration file	Template definition file
Global, nontemplate friend function of template class	Within template class declaration	Library source file
Specialization of template class	Template declaration file	
Specialization of template function	Template declaration file	Library source file

3.5.4 Creating Libraries

Libraries are useful for organizing the sources within your application as well as for providing a set of routines for other applications to use. Libraries can be either object libraries or shareable libraries. Use an object library when you want the library code to be contained within an application's image; use shareable libraries when you want multiple applications to share the same library code.

Creating a library from nontemplate code is straightforward: you simply compile each library source file and place the resulting object file in your library.

C++ Language Environment

3.5 How to Organize Your C++ Code

Creating a library from template code requires that you explicitly request the instantiations that you want to provide in your library. See Chapter 7 for details.

If you make your library available to other users, you must also supply the corresponding declarations and definitions that are needed at compile time. For nontemplate interfaces, you must supply the header files that declare your classes, functions, and global data. For template interfaces, you must provide your template declaration files as well as your template definition files.

For more information on creating libraries, see the *OpenVMS Command Definition, Librarian, and Messages Utilities Manual* and the *OpenVMS Linker Utility Manual*.

3.6 Sample Code for Creating OpenVMS Shareable Images

The SW_SHR sample code consists of several source modules, a command procedure and this description. Table 3–2 lists each of the constituent modules, which are located in the directory SYS\$COMMON:[SYSHLP.EXAMPLES.CXX] on your system.

The code creates an OpenVMS shareable image called SW_SHR.EXE that supplies a Stopwatch class identical to the C++ Class Library's Stopwatch class. For detailed information about the Stopwatch class, refer to the *HP C++ Class Library Reference Manual*, CXX_CLASSLIB.PS, in the SYS\$COMMON:[SYSHLP.CXX\$HELP] directory.

SW_SHR also provides an instance of a Stopwatch class named G_sw that shows how to export a class instance from a shareable image. The exportation occurs in the same way that cout, cin, cerr, and clog are exported from the C++ Class Library shareable image.

Table 3–2 Shareable Image Example Files

Module Name	Description
SW_SHARE.HXX	General use macros to make exporting of global data (class instances) from shareable images more transparent to the users of class objects.
SW.HXX	The definition of the Stopwatch class supplied by the shareable image.

(continued on next page)

C++ Language Environment

3.6 Sample Code for Creating OpenVMS Shareable Images

Table 3–2 (Cont.) Shareable Image Example Files

Module Name	Description
SW.CXX	Source associated with the public functions defined in SW.HXX. It also contains the declaration of the global Stopwatch (G_sw) class instance.
SW_TEST.CXX	A test of each of the Stopwatch's public access points and also the G_sw class instance.
SW_BUILD.COM	A DCL command procedure used to build both the shareable image and the program.
SW_SHR_ALPHA.OPT	An OpenVMS Linker options file, used on OpenVMS Alpha systems, that contains the SYMBOL_VECTOR entry points.
SW_SHR_IA64.OPT	An OpenVMS Linker options file, used on OpenVMS I64 systems, that contains the SYMBOL_VECTOR entry points.

In order to build the example, execute the SW_BUILD.COM procedure, then run the SW_TEST.EXE image.

When you create shared images on OpenVMS systems, you must export guard variables for template static data members or for static variables defined in inline functions. These guard variables, which are prefixed by `__SDG` and `__LSG` respectively, ensure that static data is initialized only once. You must also export the static variables in inlined functions and template static data members from the shared image so that they have only one definition.

3.7 Hints for Designing Upwardly Compatible C++ Classes

If you produce a library of C++ classes and expect to release future revisions of your library, you should consider the upward compatibility of your library. Having your library upwardly compatible makes upgrading to higher versions of your library easier for users. And if you design your library properly from the start, you can accomplish upward compatibility with minimal development costs.

The levels of compatibility discussed in this section are as follows:

1. Source compatibility
2. Link compatibility
3. Run or binary compatibility

C++ Language Environment

3.7 Hints for Designing Upwardly Compatible C++ Classes

The format in which your library ships determines the levels of compatibility that apply:

Library Format	Compatibility Level
Source format	Source compatibility only
Object format	Source and link compatibility
Shareable library format	All three kinds of compatibility

If you break compatibility between releases, you should at least document the incompatible changes and provide hints for upgrading between releases.

3.7.1 Source Compatibility

Achieving source compatibility means that users of your library will not have to make any source code changes when they upgrade to your new library release. Their applications will compile cleanly against your updated header files and will have the same run-time behavior as with your previous release.

To maintain source compatibility, you must ensure that existing functions continue to have the same semantics from the user's standpoint. In general, you can make the following changes to your library and still maintain source compatibility:

- Add new data members and classes.
- Add new virtual and nonvirtual functions (as long as they do not change overload resolution of existing calls).
- Loosen protection.
- Change inline functions to out-of-line, and out-of-line functions to inline.
- Change the implementation of functions.
- Add arguments with default values to existing member functions.

3.7.2 Link Compatibility

Achieving link compatibility means that users of your library can relink an application against your new object or shareable library and not be required to recompile their sources.

C++ Language Environment

3.7 Hints for Designing Upwardly Compatible C++ Classes

What Can Change

To maintain link compatibility, the internal representation of class objects and interfaces must remain constant. In general, you can make the following changes to your library and still maintain link compatibility:

- Change anything that is invisible to the user.
- Change the implementation of an out-of-line function.
- Loosen protection.
- Add a new nonvirtual member function (as long as it does not change overload resolution for existing calls).

What Cannot Change

Because the user may be linking object modules from your previous release with object modules from your new release, the layout and size of class objects must be consistent between releases. Any user-visible interfaces must also remain unchanged; even the seemingly innocent change of adding `const` to an existing function will change the mangled name and thus break link compatibility.

The following are changes that you cannot make in your library:

- Add, move, or delete data members.
- Add, move, or delete virtual functions.
- Change the signature of virtual and nonvirtual functions.
- Remove nonvirtual functions.
- Change inline function definitions.
- Change functions from out-of-line to inline.

Designing Your C++ Classes for Link Compatibility

Although the changes you are allowed to make in your library are severely restricted when you aim for link compatibility, you can take steps to prepare for this and thereby reduce the restrictions. HP suggests using one of the following design approaches:

- Set aside dummy (reserved-for-future-use) data fields and virtual functions within your classes. This assumes you can foresee how much your classes will grow and change in the future.

C++ Language Environment

3.7 Hints for Designing Upwardly Compatible C++ Classes

- Add a level of indirection to hide your virtual functions and data fields from the user. This lets you add and change data fields and virtual functions without affecting the library user; however, there may be some disadvantages such as in performance. This approach is detailed in *Effective C++*, Section 34, by Scott Meyers.

3.7.3 Run Compatibility

Achieving run compatibility means that users of your library can run an application against your new shareable library and not be required to recompile or relink the application.

This requires that you follow the guidelines for link compatibility as well as any operating system guidelines for shareable libraries. On OpenVMS systems, you need to create an upwardly compatible shareable image using a transfer vector on OpenVMS VAX and a symbol table on OpenVMS Alpha. Refer to the *OpenVMS Linker Utility Manual* for information on creating a shareable image.

3.7.4 Additional Reading

The C++ Programming Language, 3rd Edition offers some advice on compatibility issues. Another good reference is *Designing and Coding Reusable C++*, Chapter 7, by Martin D. Carroll and Margaret E. Ellis.

4

Porting to I64 Systems

This chapter describes some of the differences and restrictions you might encounter when porting the HP C++ compiler to an I64 system. For a summary of new and changed features supported by this version of the compiler on both OpenVMS Alpha and I64 systems, see the Preface of this manual. For any known issues, see the C++ release notes.

HP C Version 7.1 for OpenVMS I64 uses a new technology base that differs substantially from HP C++ for OpenVMS Alpha and HP C for OpenVMS I64. Although a great deal of work has been done to make it highly compatible with HP C++ for OpenVMS Alpha, there are a number of differences that you will likely notice. Among them are:

- Resource requirements.
Programs will usually use more memory, both at compile time and at run time. See Section 4.1.2.
- Floating-point behaviors.
The default on I64 systems is `/FLOAT=IEEE/IEEE_MODE=DENORM_RESULTS`. Consistent use of qualifiers across compilations is required. See Section 4.1.6.
- Simplified instantiation without repository. See Section 4.1.9.
- No inline assembly language. See Section 4.1.7.
- String literal type change.
For standards-compliance and link compatibility between compiler dialects, ordinary string literals now have the type "array of const char" in all compiler dialects on I64 systems in all compiler modes and on Alpha systems in `/MODEL=ANSI` mode.
In `/MODEL=ARM` mode on Alpha systems, string literals are of type "array of char" in all compiler dialects.

Porting to I64 Systems

4.1 Compiler Considerations

4.1 Compiler Considerations

This section describes porting considerations for the C++ compiler for OpenVMS I64 systems. See Section 4.2 for considerations for the standard library, language run-time support library, and class library.

4.1.1 Messages

The move from Alpha systems to I64 systems may cause some minor differences in certain compiler diagnostics that are signaled from the code generator. As a result, diagnostics for unreachable code and fetches of uninitialized variables might be different on the two platforms. In addition to a change in message text, some conditions detected on one platform might not be detected on the other.

There have also been some changes in the `/WARNINGS` qualifier for both platforms. These include bug fixes and improved compatibility with the C compiler. For a summary of these changes, see the New and Changed Features section of the Preface.

4.1.2 Quotas

The C++ compiler for I64 systems is built from a different code base than the C++ compiler for Alpha systems, and that code base is larger than the code base for Alpha. Also, I64 images tend to be somewhat larger than Alpha images in general. Image size mostly affects working-set size and the amount of pagefile quota needed to execute an image without exhausting virtual memory. If you find that programs that compile and run successfully on Alpha run out of memory on I64 systems (either during compilation or when run), you probably need to increase your pagefile quota. There are no specific guidelines at this time. You might start by doubling the quota that was sufficient on Alpha, and then use a "binary-search" approach to arrive at a better quota value for I64 systems (doubling again, or halving the increment, until your biggest programs and compilations have just enough memory, and then adding an appropriate safety margin).

4.1.3 Dialect Changes

Some of the compiler dialects (options to the `/STANDARD` qualifier) have been updated to reflect the most recent behaviors of the compilers that the dialect is attempting to match. Other changes involve the removal of less significant or undesirable compatibility features.

Porting to I64 Systems

4.1 Compiler Considerations

4.1.4 ABI/Object Model changes

The object model and the name mangling scheme used by the C++ compiler on I64 systems are different from those used on Alpha systems (different from both /MODEL=ARM and /MODEL=ANSI). The I64 compiler uses the interface described by the I64 Application Binary Interface (ABI).

See <http://www.codesourcery.com/cxx-abi/abi.html> for a draft description of the ABI specification.

The C++ compiler has some additional encoding rules that are applied to symbol names after the ABI name mangling is determined. All symbols with C++ linkage have CRC encodings added to the name, are uppercased and shorten to 31 characters if necessary. Since the CRC is computed before the name is uppercased, the symbol name is case-sensitive even though the final name is in uppercase. /NAMES=AS_IS and /NAMES=UPPER are not applicable to these symbols.

All symbols without C++ linkage will have CRC encodings added if they are longer than 31 characters and /NAMES=SHORTEN is specified. Global variables with C++ linkage are treated as if they have non-C++ linkage for compatibility with C and older compilers.

4.1.5 Command-Line Qualifiers

This section describes C++ command-line qualifier differences to be aware of on I64 systems.

Qualifiers/Features Not Supported on I64 Systems

The following command-line qualifiers and features are not supported on C++ for I64 systems, and are diagnosed by default because ignoring them is likely to alter program behavior:

- Comma lists are not supported. Their use provokes a fatal error.
- /INSTRUCTION_SET=NOFLOATING_POINT is not available on I64 systems. If it is specified, a warning message is issued, and /INSTRUCTION_SET=FLOATING_POINT is used.
- /L_DOUBLE_SIZE=64 is not available on I64 systems. If it is specified, a warning message is issued, and /L_DOUBLE_SIZE=128 is used.

Porting to I64 Systems

4.1 Compiler Considerations

Changed/Ignored Qualifiers

A number of other qualifiers not supported on I64 systems are, by default, silently ignored by the compiler. These qualifiers fall into two groups:

- Qualifiers that should not alter the behavior of a correct program and so, if ignored, should have no visible effect. Qualifiers that enable optimizations typically have this characteristic.
- Qualifiers that might affect program behavior but, if ignored, produce no significant change in the vast majority of programs. Examples of qualifiers in this category are `/NORTTI` (the runtime information is always generated) and `/MODEL=ARM` (the ANSI model is functionally superior, and binary compatibility with existing object code is not an issue for the OpenVMS I64 platform).

Two optional compiler messages can be enabled to diagnose most of these cases:

- The `QUALNA` message diagnoses uses of the first group.
- The `QUALCHANGE` message diagnoses uses of the second group.

If you encounter porting problems, compile `/WARN=ENABLE=QUALCHANGE` to determine if a qualifier change might be affecting your application.

If you wish to clean up your build scripts to remove extraneous qualifiers that are not meaningful on I64 systems, you can enable the `QUALNA` message.

A list of these qualifiers follows:

- `/ARCHITECTURE=option`

An additional keyword has been added: `ITANIUM2`.

If an Alpha keyword (`EV4`, `EV5`, `EV56`, `PCA56`, `EV6`, `EV68`, `EV7`) is specified for *option*, it is ignored.

- `/ASSUME`

The following `/ASSUME` options are ignored on I64 systems and should not cause any behavior changes:

```
NORTTI_CTORVTBLS
NOPOINTERS_TO_GLOBALS
TRUSTED_SHORT_ALIGNMENT
WHOLE_PROGRAM
```

- `/CHECK=UNINITIALIZED_VARIABLES`

This qualifier has no effect in this version of the compiler.

- `/DEBUG`

Porting to I64 Systems

4.1 Compiler Considerations

The following debug options are ignored:

```
/DEBUG=NOSYMBOLS  
/DEBUG=NOTRACEBACK
```

- /DISTINGUISH_NESTED_ENUMS

This qualifier only modified the behavior of programs compiled with /MODEL=ARM. Since that model is not supported on the I64 platform, this qualifier is meaningless.

- /EXCEPTIONS=NOCLEANUP

The NOCLEANUP keyword for the /EXCEPTIONS qualifier is ignored.

- /EXCEPTIONS=IMPLICIT

The IMPLICIT keyword for the /EXCEPTIONS qualifier is ignored.

- /FLOAT

The default for /FLOAT on OpenVMS I64 systems is IEEE_FLOAT.

See Section 4.1.6 for more information about floating-point behavior on I64 systems.

- /IEEE_MODE

The default for /IEEE_MODE on I64 systems is DENORM_RESULTS, which generates infinities, denorms, and NaNs without exceptions.

On OpenVMS Alpha systems, the default for /IEEE_MODE when using /FLOAT=IEEE_FLOAT is FAST, which causes a FATAL error for exceptional conditions such as divide-by-zero and overflow.

See Section 4.1.6 for more information.

- The /MODEL=ARM qualifier is treated the same as the default /MODEL=ANSI (except for the optional QUALCHANGE diagnostic).

- /OPTIMIZE

There are several changes to the /OPTIMIZE qualifier:

- On I64 systems, for /OPTIMIZE=INLINE, the keywords AUTOMATIC and SPEED do the same thing.

Also, the ALL keyword does not necessarily result in every possible call being inlined, as it does on Alpha systems.

- The /OPTIMIZE=TUNE qualifier takes a new keyword: ITANIUM2, which is the default at this time. If you specify an Alpha keyword, it is ignored.

Porting to I64 Systems

4.1 Compiler Considerations

- The `/OPTIMIZE=UNROLL=n` qualifier is not very useful on I64 systems. Because of this, specifying an unroll value greater than 0 is simplified to mean that simple loop unrolling is enabled. On I64 systems, the user does not have the ability to control the number of times a loop is unrolled.
- `/OPTIMIZE=LIMIT_INLINE` is ignored.
- `/TEMPLATE`
See Section 4.1.9 for information on template instantiation.
- `/SHOW=STATISTICS`
The `/SHOW=STATISTICS` qualifier is ignored at this time.
- `/STANDARD=CFRONT`
The `/STANDARD=CFRONT` qualifier is no longer available. If it is specified, the compiler issues a warning message and uses the default dialect, `/STANDARD=ANSI`.

New Qualifiers

The following command-line qualifier is new for C++ Version 7.1:

- `/[NO]PURE_CNAME`
This qualifier affects insertion of the names into the global namespace by `<cname>` headers.
In `/PURE_CNAME` mode, the `<cname>` headers insert the names into the `std` namespace only, as defined by the C++ Standard, and the `__PURE_CNAME` macro is predefined by the compiler.
In `/NOPURE_CNAME` mode, the `<cname>` headers insert the name into the `std` namespace and also into the global namespace.
The default depends on the standard mode:
 - In `/STANDARD=STRICT_ANSI` mode, the default is `/PURE_CNAME`.
 - In all other standard modes, the default is `/NOPURE_CNAME`.Inclusion of a `<name.h>` header instead of its `<cname.h>` counterpart (for example, `<stdio.h>` instead of `<cstdio>`) results in inserting names defined in the header into both the `std` namespace and the global namespace. Effectively, this is the same as the inclusion of a `<cname>` header in the `/NOPURE_CNAME` mode.
See Section 3.1 for more information.

Porting to I64 Systems

4.1 Compiler Considerations

4.1.6 Floating Point

This section describes floating-point behavior on I64 systems.

IEEE Now the Default

On OpenVMS I64 systems, `/FLOAT=IEEE_FLOAT` is the default floating-point representation. IEEE format data is assumed and IEEE floating-point instructions are used. There is no hardware support for floating-point representations other than IEEE, although you can specify the `/FLOAT=D_FLOAT` or `/FLOAT=G_FLOAT` compiler option.

These VAX floating-point formats are supported in the I64 compiler by generating run-time code that converts VAX floating-point formats to IEEE format to perform arithmetic operations, and then converts the IEEE result back to the appropriate VAX floating-point format. This imposes additional run-time overhead and some loss of accuracy compared to performing the operations in hardware on Alpha and VAX systems. The software support for the VAX formats is provided to meet an important functional compatibility requirement for certain applications that need to deal with on-disk binary floating-point data.

On I64 systems, the default for `/IEEE_MODE` is `DENORM_RESULTS`, which is a change from the default of `/IEEE_MODE=FAST` on Alpha systems. This means that by default, floating-point operations may silently generate values that print as Infinity or Nan (the industry-standard behavior), instead of issuing a fatal run-time error as they would when using VAX floating-point format or `/IEEE_MODE=FAST`. Also, the smallest-magnitude nonzero value in this mode is much smaller because results are allowed to enter the denormal range instead of being flushed to zero as soon as the value is too small to represent with normalization.

The conversion between VAX floating-point formats and IEEE formats on the Intel Itanium architecture is a transparent process that will not impact most applications. All you need to do is recompile your application. Because IEEE floating-point format is the default, unless your build explicitly specifies VAX floating-point format options, a simple rebuild for I64 systems will use the native IEEE formats directly. For the large class of programs that do not directly depend on the VAX formats for correct operation, this is the most desirable way to build for I64 systems.

When you compile an OpenVMS application that specifies an option to use VAX floating-point on an I64 system, the compiler automatically generates code for converting floating-point formats. Whenever the application performs a sequence of arithmetic operations, this code does the following:

Porting to I64 Systems

4.1 Compiler Considerations

1. Converts VAX floating-point formats to either IEEE single or IEEE double floating-point formats.
2. Performs arithmetic operations in IEEE floating-point arithmetic.
3. Converts the resulting data from IEEE formats back to VAX formats.

Where no arithmetic operations are performed (VAX float fetches followed by stores), no conversion will occur. The code handles such situations as moves.

VAX floating-point formats have the same number of bits and precision as their equivalent IEEE floating-point formats. For most applications, the conversion process will be transparent and, therefore, a non-issue.

In a few cases, arithmetic calculations might have different results because of the following differences between VAX and IEEE formats:

- Values of numbers represented
- Rounding rules
- Exception behavior

These differences might cause problems for applications that do any of the following:

- Depend on exception behavior
- Measure the limits of floating-point behaviors
- Implement algorithms at maximal processor-specific accuracy
- Perform low-level emulations of other floating-point processors
- Use direct equality comparisons between floating-point values, instead of appropriately ranged comparisons (a practice that is extremely vulnerable to changes in compiler version or compiler options, as well as architecture)

You can test an application's behavior with IEEE floating-point values by first compiling it on an OpenVMS Alpha system using `/FLOAT=IEEE_FLOAT/IEEE_MODE=DENORM`.

If that produces acceptable results, then simply build the application on the OpenVMS I64 system using the same qualifier.

If you determine that simply recompiling with an `/IEEE_MODE` qualifier is not sufficient because your application depends on the binary representation of floating-point values, then first try building for your I64 system by specifying the VAX floating-point option that was in effect for your VAX or Alpha build. This causes the representation seen by your code and on disk to remain unchanged, with some additional runtime cost for the conversions generated

Porting to I64 Systems

4.1 Compiler Considerations

by the compiler. If this is not an efficient approach for your application, you can convert VAX floating-point binary data in disk files to IEEE floating-point formats before moving the application to an I64 system.

/IEEE_MODE Notes

On Alpha systems, the `/IEEE_MODE` qualifier generally has its greatest effect on the generated code of a compilation. When calls are made between functions compiled with different `/IEEE_MODE` qualifiers, each function produces the `/IEEE_MODE` behavior with which it was compiled.

On I64 systems, the `/IEEE_MODE` qualifier primarily affects only the setting of a hardware register at program startup. In general, the `/IEEE_MODE` behavior for a given function is controlled by the `/IEEE_MODE` option specified on the compilation that produced the main program: the startup code for the main program sets the hardware register according to the command-line qualifiers used to compile the main program.

When applied to a compilation that does not contain a main program, the `/IEEE_MODE` qualifier does have some effect: it might affect the evaluation of floating-point constant expressions, and it is used to set the `EXCEPTION_MODE` used by the math library for calls from that compilation. But the qualifier has no effect on the exceptional behavior of floating-point calculations generated as inline code for that compilation. Therefore, if floating-point exceptional behavior is important to an application, all of its compilations, including the one containing the main program, should be compiled with the same `/IEEE_MODE` setting.

Even on Alpha systems, the particular setting of `/IEEE_MODE=UNDERFLOW_TO_ZERO` has the following characteristic: its primary effect requires the setting of a runtime status register, and so it needs to be specified on the compilation containing the main program in order to be effective in other compilations.

More Information

For more information on I64 floating-point behavior, see the white paper *OpenVMS floating-point arithmetic on the Intel Itanium architecture* at http://www.hp.com/products1/evolution/alpha_retaintrust/download/i64-floating-pt-wp.pdf.

4.1.7 Intrinsics and Builtins

The C++ built-in functions available on OpenVMS Alpha systems are also available on I64 systems, with some differences. Section C.2 documents these differences and describes the built-in functions that are specific to I64 systems.

Porting to I64 Systems

4.1 Compiler Considerations

4.1.8 ELF

On OpenVMS Alpha systems, the C++ compiler uses a proprietary object format specific to OpenVMS.

On OpenVMS I64 systems, the compiler generates ELF objects. ELF is an industry standard object format used on many UNIX platforms, including Linux. This change should be transparent to most users; it is primarily of interest to compiler and tools developers. The greatest benefit of this change is that it should make it easier to create development tools that work on OpenVMS and other platforms.

Extensions to ELF have been used as needed to provide functionality unique to OpenVMS. See the *Porting Applications from HP OpenVMS Alpha to HP OpenVMS Industry Standard 64 for Integrity Servers* for more information on ELF.

COMDATS/Group Sections

One feature that ELF provides that is new to OpenVMS is the COMDAT section group—a group of sections in an object file that can be duplicated in one or more other object files. The linker is expected to keep one group and ignore all others. The benefit of this feature is that it permits compilers to generate definitions for symbols for things used in multiple objects without having to worry about creating a single definition in one place. The most notable uses for this feature are templates and inline functions.

New ELF Type for Weak Symbols

A new Executable and Linkable Format (ELF) type was generated to distinguish between the two types of weak symbol definitions.

For modules with ABI versions equal to 2 (the most common version used by compilers):

- Type STB_WEAK represents the UNIX-style weak symbol (formerly, the OpenVMS-style weak symbol definition for ABI Version 1 ELF format).
- Type STB_VMS_WEAK represents the OpenVMS-style of weak symbol definition.

The Librarian supports both the ELF ABI versions 1 and 2 of the object and image file formats within the same library.

Porting to I64 Systems

4.1 Compiler Considerations

4.1.9 Templates

This section describes template instantiation for I64 systems.

Implemented using ELF COMDATS/Groups Sections

The Alpha C++ compiler had numerous models for instantiating templates. Each attempted to solve the issue of how to generate one and only one copy of each template. The use of ELF on OpenVMS I64 systems provided the compiler with the additional option of using COMDAT section groups. Since this technique is superior to all the models supported on Alpha, this is the only model supported on I64 systems.

In this model, templates are instantiated in a COMDAT section group inside every object module that uses them. This is very similar to the `/TEMPLATE=LOCAL` on Alpha systems, except that when the objects are linked together, the linker removes the duplicate copies. The primary advantage of this technique over `/TEMPLATE=LOCAL` and `/TEMPLATE=IMPLICIT_LOCAL` is the reduction in image size.

A secondary advantage is the elimination of distinct data for each template. For example, if a template maintained a list of elements it created, each module would have a separate copy of the list. This behavior does not conform to the standard. If you are currently using `/TEMPLATE=LOCAL` or `/TEMPLATE=IMPLICIT_LOCAL`, you will likely experience no difficulty from this change.

Not in Repository

The most visible difference that results from this new instantiation model occurs in models that instantiate templates into the repository (`/TEMPLATE=AUTOMATIC | ALL_REPOSITORY | USED_REPOSITORY`).

With the new model, no repository is needed. Build procedures that use CXXLINK will work transparently. Builds that attempt to manipulate objects in the repository will fail and will need to be changed. In most cases, the reason for manipulating the repository directly has been eliminated with the new template instantiation model.

Also see Chapter 5.

Porting to I64 Systems

4.1 Compiler Considerations

4.1.10 Exceptions and Condition Handlers

The command-line option `/EXCEPTIONS=NOCLEANUP` is not implemented. As a result, you might see destructors being called during cleanup in code previously compiled with this option.

Exception specifications are not implemented. Exception specifications on routine declarations and definitions are accepted syntactically, but their run-time behavior has not yet been implemented.

4.1.10.1 Stack unwinding

According to the C++ Standard, an implementation may or may not unwind the stack before calling `terminate` when no matching handler is found for a thrown exception. On I64 systems, the implementation unwinds the stack. On Alpha systems, it does not.

Consider the following program:

```
#include <exception>
#include <cstdio>
#include <cstdlib>

class C {
public:
    C() { std::printf("Created\n"); }
    ~C() { std::printf("Destroyed\n"); }
};

void announce1() {
    std::printf("In terminate\n");
    exit(0);
}

int main() {
    C c;
    std::set_terminate(announce1);
    throw 5;
    return 0;
}
```

For the above program, the output on OpenVMS Alpha and I64 systems is:

Alpha:	I64:
Created	Created
In terminate	Destroyed
	In terminate

Porting to I64 Systems

4.1 Compiler Considerations

4.1.10.2 Exceptions Not Caught

The compiler assumes that the only two ways an exception can be propagated into a function are:

- From a throw expression, or
- From a routine call that itself can throw an exception.

As a result of this assumption, some exceptions such as those thrown from a signal handler will not be caught.

4.1.10.3 terminate() Incorrectly Called

The C++ I64 compiler incorrectly calls `terminate()` when, during unwinding, the destruction of an object results in an exception, even if this exception is caught within the destructor.

For example, consider the following program:

```
extern "C" int printf(const char *,...);

struct killit {
    killit () {}
    ~killit () {
        try {
            throw 11;
        } catch (int i) {
            printf("caught %d\n", i);
        }
    }
};

int main () {
    try {
        killit local;
        throw 33;
    } catch (const int &i) {
        printf("caught int: %d\n", i);
    }

    return 0;
}
```

The expected output for the above example is:

```
caught 11
caught int: 33
```

But the executable produced by the C++ I64 compiler calls `terminate()`.

Porting to I64 Systems

4.1 Compiler Considerations

In cases where the expression to be thrown has been evaluated, but before the exception can be caught: if a called user function such as a copy constructor exits through an uncaught exception, then the compiler incorrectly attempts to match this latter exception object type to the handlers in enclosing try blocks in succession, instead of calling `terminate()`.

Further, the function `uncaught_exception` returns `FALSE` while in the called user function described above.

For example, consider the following program:

```
extern "C" int printf(const char *,...);
extern "C" int exit(int);
#include <exception>

void announce () {
    printf("Terminated!\n");
    exit(0);
}

class Y {
public:
    Y () { printf ("construct Y\n"); }
    Y(Y &rhs) {
        printf ("copy Y\n");
        printf ("uncaught_exception = %s\n", std::uncaught_exception() ?
            "TRUE" : "FALSE");
        throw 20;
    }
    ~Y () { printf ("destruct Y\n"); }
};

void cxx_func () {
    Y OBJ2;
    printf ("In cxx_func\n");
    try {
        throw OBJ2;
    } catch (const Y &) {
        printf("Caught Y &\n");
    } catch (int i) {
        printf("Caught %d\n", i);
    }
    printf ("leaving cxx_func\n");
}

main () {
    std::set_terminate(announce);
    cxx_func();
    printf ("Leaving main\n");
}
```

Porting to I64 Systems

4.1 Compiler Considerations

The expected output in the above example is:

```
construct Y
In cxx_func
copy Y
uncaught_exception = TRUE
Terminated!
```

But the executable produced by the C++ I64 compiler outputs:

```
construct Y
In cxx_func
copy Y
uncaught_exception = FALSE
Caught 20
leaving cxx_func
destruct Y
Leaving main
```

The C++ I64 compiler also incorrectly calls `terminate()` when a destructor invoked during stack unwinding exits with an exception that violates its own exception specification, instead of calling `unexpected()`.

Consider the following program:

```
#include <exception>
extern "C" void exit(int);
extern "C" int printf(const char *,...);

void announce2 () {
    printf("announce2: Unexpected!\n");
    exit(0);
}

void announce1 () {
    printf("announce1: Terminated!\n");
    exit(0);
}

class C {
public:
    C() { printf("C()\n"); }
    ~C() throw() { std::set_unexpected(announce2); printf("~C()\n"); throw 3; }
};

void foo() {
    C c;
    printf("throwing ...\n");
    throw 5;
}
```

Porting to I64 Systems

4.1 Compiler Considerations

```
main() {
    std::set_terminate(announce1);
    foo();
}
```

In the above example, the expected output is:

```
C()
throwing ...
~C()
announce2: Unexpected!
```

But the executable produced by the C++ I64 compiler outputs:

```
C()
throwing ...
~C()
announce1: Terminated!
```

4.1.10.4 Problem in unexpected() Behavior

When a user-defined `unexpected()` routine throws or rethrows an exception, the compiler incorrectly checks the exception specification of the caller of the routine instead of that of the routine itself, which did not allow the exception in its exception specification.

Consider the following program:

```
#include <exception>
#include <cstdlib>

extern "C" int printf(const char *, ...);

void my_unex() {
    printf("In my unex\n");
    throw;
}

void my_term() {
    printf("In my term\n");
    std::exit(0);
}

void foo() throw() { // spec not checked with second rethrow
    printf("In foo\n");
    throw 7;
}

void bar() throw(int) { // this spec checked with second rethrow
    printf("In bar\n");
    foo();
}
```

Porting to I64 Systems

4.1 Compiler Considerations

```
void foo2() throw(std::bad_exception) { // spec not checked with first rethrow
    printf("In foo2\n");
    throw 5;
}

int main() {
    std::set_unexpected(my_unex);
    std::set_terminate(my_term);
    try {
        foo2();
    } catch (int i) {
        printf("Caught %d\n", i);
    } catch (std::bad_exception &) {
        printf("Caught bad_exception\n");
    }

    try {
        bar();
    } catch (int i) {
        printf("Caught %d\n", i);
    } catch (...) {
        printf("Caught ... \n");
    }
    return 0;
}
```

In the above example, expected output is:

```
In foo2
In my unex
Caught bad_exception
In bar
In foo
In my unex
In my term
```

But the compiler produces:

```
In foo2
In my unex
Caught 5
In bar
In foo
In my unex
Caught 7
```

Porting to I64 Systems

4.2 Library Changes

4.2 Library Changes

For I64 systems, the C++ standard library has been upgraded and organized as a shareable image. All applicable fixes and enhancements done in the C++ standard library for Alpha systems, have been applied to the C++ standard library for I64 systems.

The C++ class library on I64 systems is based on the same code as the C++ class library on Alpha systems. The major change in the C++ class library for I64 systems is the removal of the tasks and complex packages.

4.2.1 Library Reorganization

The standard library, language run-time support library, and class library have been reorganized for I64 systems.

4.2.1.1 Standard Library and Language Run-Time Support Library

On Alpha systems, the C++ standard library and language run-time support library is delivered in an object library, LIBCXXSTD.OLB, shipped with the compiler kit.

On I64 systems, the C++ standard library and language run-time support library are delivered as separate system shareable images shipped with the base operating system. The names of the images are: CXXL\$RWRTL.EXE and CXXL\$LANGRTL.EXE, respectively. The images reside in the SYS\$LIBRARY directory and are installed at system startup. The LIBCXXSTD.OLB object library does not exist on I64 systems.

4.2.1.2 Class Library

On Alpha systems, there are three class library shareable images: CXXL\$011_SHR.EXE, CXXL\$011_SHRTASK.EXE, and CXXL\$011_TASK.EXE.

On I64 systems, the C++ class library continues to ship as a system shareable image. Because the tasks and complex packages have been removed, there is only one class library image: CXXL\$011_SHR.EXE.

4.2.2 Language Run-Time Support Library

The language run-time support library no longer validates if a negative value has been specified in a call to operator `new`. Instead, the value is treated as an unsigned value, and an attempt is made to dynamically allocate the specified memory.

4.2.3 Class Library

The following class library changes have been made:

- The tasks and complex packages have been removed. The recommended replacements are the pthreads routines and complex template class, respectively, from the C++ standard library.
- In the String class, the `char*()` operator, which converts String to a pointer to char, has been removed. The String class has a `const char*()` operator, which can be used instead of the removed one.

4.2.4 Standard Library

This section describes changes to the C++ standard library.

4.2.4.1 Changes

There are two major changes in the C++ standard library for I64 systems as compared with the standard library for Alpha systems:

- The C++ standard library has been upgraded from Version 2.0 of the Rogue Wave C++ Standard Library to Version 3.0.
- The C++ standard library is delivered with the operating system as the installed system shareable image `SYS$SHARE:CXXL$RWRTL.EXE`, and also in `STARLET.OLB` in the object form for linking `/NOSYSSHARE`. On I64 systems, there is no `LIBCXXSTD.OLB`, which is the object library where the C++ standard library for OpenVMS Alpha resides.

Additional standard library changes, known issues, and platform differences are noted in the following sections.

4.2.4.2 Library Headers

While the change in the library distribution model should be transparent to customers (except that application images are much smaller on I64 systems), users on I64 systems may find that the new C++ Standard Library is much less forgiving in terms of including all necessary library headers than the old Standard Library.

For example, the following program compiles cleanly on OpenVMS Alpha systems despite the fact that it does not include the `<iostream>` header necessary for the `std::cout` object:

Porting to I64 Systems

4.2 Library Changes

```
#ifndef __USE_STD_Iostream
#define __USE_STD_Iostream
#endif
#include <fstream>

using namespace std;

main() {
    cout << "hello, world";
}
```

However, on OpenVMS I64 systems, compilation fails with the following error:

```
%CXX-E-UNDECLARED, identifier "cout" is undefined
```

It is nearly impossible to describe all combinations of library constructs and header files that would compile cleanly on Alpha systems and yet fail to compile on I64 systems because a library header required by the C++ standard for a particular construct has not been included. If a program that used to compile cleanly on an Alpha system fails to compile on an I64 system, it is always a good idea to check that all necessary library headers are included.

4.2.4.3 Internal Library Headers and Macros

A program that includes internal RW stdlib V2.0 library headers, like `<stddefs>` or `<stdcomp>`, or that uses internal library macros `_RW_*`, will have to be modified because the new C++ standard library does not necessarily have the same internal headers or use the same internal macros as the old one.

4.2.4.4 Known Issues and Restrictions

The following are known issues with C++ for OpenVMS I64 systems:

- The C++ Standard Library IOStreams expect floating-point values in the IEEE format, which is the default floating-point format on I64 systems. Using the Standard Library IOStreams for processing floating-point values in a format other than IEEE (for example, in a program compiled with the `/FLOAT=G_FLOAT` or `/FLOAT=D_FLOAT` qualifier) is not supported. The C++ class library does not have this restriction.

4.2.4.5 Differences Between Alpha and I64 Systems

The following are differences between the I64 and Alpha standard libraries:

- On OpenVMS Alpha systems, the following constructors for the C++ standard library classes `strstream` and `ostrstream` initialize `ptr[count-1]` with a null byte:

Porting to I64 Systems 4.2 Library Changes

```
strstream(char *ptr, streamsize count,  
          ios_base::openmode mode = ios_base::in | ios_base::out);  
ostrstream(char *ptr, streamsize count,  
           ios_base::openmode mode = ios_base::out);
```

This initialization is not required by the C++ standard, and on I64 systems the C++ standard library does not do it.

- On I64 systems, map and multimap containers require the standard-conformant form of allocator class: `allocator<pair<const Key, T> >`.

For example, on Alpha systems, it is possible to declare an object of class `multimap` as the following, with the second template argument of allocator class omitted:

```
multimap<string, int, less<string>, allocator<string> > x;
```

But for I64 systems, this must be changed to:

```
multimap<string, int, less<string>, allocator<pair<const string, int> > > x;
```

- On I64 systems, the `exception.what()` function reports the module name, and the message text might be different.

For example, an output on Alpha systems:

```
Got an exception: string index out of range in function:  
basic_string::replace(size_t,size_t,size_t,char) position: 100 is  
greater than length: 0
```

An output on I64 systems:

```
Got an exception: CSRC:[STDIPF_INCLUDE]STRING.CC;:416:  
basic_string::replace(size_type, size_type, size_type, value_type):  
argument value 100 out of range [0, 0)
```

- On I64 systems, `iostreams` extraction operators truncate out-of-range integer values to the maximum possible value for a given type, and set the failbit for the stream.

For example, consider the following program:

```
#ifndef __USE_STD_Iostream  
#define __USE_STD_Iostream  
#endif  
  
#include <strstream>  
#include <iostream>  
  
using namespace std;
```

Porting to I64 Systems

4.2 Library Changes

```
main() {
    istrstream is("32768"); // SHRT_MAX is 32767
    short s;
    is >> s;
    cout << is.fail() << endl;
    cout << s << endl;
}
```

On Alpha systems, this program gives:

```
0
-32768
```

On I64 systems, it gives:

```
1
32767
```

Note that on I64 systems, the failbit for the stream is set.

According to the C++ Standard, Section 22.2.2.1 - Template class `num_get` [`lib.locale.num.get`], an input that would have caused `scanf` to report an input failure should result in setting `ios_base::failbit` to `err`. Since on OpenVMS, `scanf` reports an input failure in this case (this is an undefined behavior from the point of view of the C standard), the behavior of the C++ standard library on I64 systems is standard-compliant.

- On Alpha systems, the `find` template function is implemented using `operator!=`. On I64 systems, this function is implemented using `operator==`, which according to the C++ standard is the operator the `find` function should be using.

Consequently, if no conversion from `*InputIterator` to `T` exists, on Alpha systems the following function can be instantiated only if `operator!=(*InputIterator,T)` exists:

```
find(InputIterator first, InputIterator last, const T& value)
```

On I64 systems, however, the function can be instantiated only if `operator==(*InputIterator,T)` exists.

The following program illustrates the difference. If you comment out the line `bool operator!=(S, int);`, the program does not compile on Alpha systems. If you comment out the line `bool operator==(S, int);`, the program does not compile on I64 systems. The behavior on I64 systems is the standard-conformant behavior.

Porting to I64 Systems 4.2 Library Changes

```
include <algorithm>
#include <vector>

struct S {
    int i;
};

bool operator!=(S, int);
bool operator==(S, int);

void foo() {
    std::vector<S> v;
    std::find(v.begin(), v.end(), 0);
}
```

- On I64 systems, an attempt to write into a stream opened for read (`ios::in`), causes the stream `badbit` bit to be set.

On both Alpha and IPF systems, nothing is written into a stream opened for read. However, on Alpha systems, the stream `badbit` bit is not set.

The C++ standard does not provide explicit guidance about what to do in this case. However, the behavior on I64 systems is more reasonable—at least there is an indication that something was wrong.

- On I64 systems, `reverse_iterator` cannot be instantiated on `vector<bool>::iterator` type.

For example, the following program, which compiles cleanly on Alpha systems, does not compile on I64 systems:

```
#include <vector>

typedef std::reverse_iterator<std::vector<bool>::iterator> ri;

main()
{
    ri::pointer (ri::*foo)() const = &ri::operator->;
}
```

A recently adopted resolution for the library issue 120 has made this construct invalid. See <http://std.dkuug.dk/JTC1/SC22/WG21/docs/lwg-active.html#120> for more details.

- On I64 systems, for a random access iterator, `operator-(const random_access_iterator&)` returning `difference_type` must be `const`.

For example, the following program compiles cleanly on Alpha systems. However, on I64 systems it compiles only if `// const` is uncommented.

Porting to I64 Systems

4.2 Library Changes

```
#include <algorithm>

template <class T> class randomaccessiterator {
public:
    typedef T value_type;
    typedef int difference_type;
    typedef T* pointer;
    typedef T& reference;
    typedef std::random_access_iterator_tag iterator_category;

    bool operator==(const randomaccessiterator&);
    bool operator!=(const randomaccessiterator&);
    T& operator*() const;
    T* operator->();

    randomaccessiterator& operator++();
    const randomaccessiterator& operator++(difference_type);
    randomaccessiterator& operator--();
    const randomaccessiterator& operator--(difference_type);
    randomaccessiterator& operator+=(difference_type);
    randomaccessiterator& operator+(difference_type);
    randomaccessiterator& operator-=(difference_type);
    randomaccessiterator& operator-(difference_type);
    difference_type operator-(const randomaccessiterator&); // const;
};

struct S {};
typedef randomaccessiterator<S> Iterator;
typedef bool (*Predicate)(Iterator::value_type);
template Iterator std::stable_partition<Iterator, Predicate>(Iterator,
Iterator, Predicate);
```

Table 76 in the C++ standard specifies the requirements for a random access iterator. It says the expression $b - a$ must be valid, where a and b denote values of X , the random access iterator. It is not completely clear from the standard whether values of X also imply `const` values of X , but if the answer is yes, the behavior on I64 systems is correct.

- On I64 systems, an attempt to call the `strstream.seekg(0)` function for an empty stream (the one whose 'next' pointer is `NULL`) causes the stream failbit to be set.

This is a standard-compliant behavior. Notice that after the failbit is set for the stream, the `strstream.str()` function returns a `NULL` pointer.

- On I64 systems, after a call to `string.resize(newsize)`, `string.capacity()` does not necessarily return `newsize`.

While on Alpha systems the `string.capacity()` function returns `newsize`, this is not required by the C++ standard. A program relying on Alpha behavior should be modified to call the `string.size()` function instead.

Porting to I64 Systems 4.2 Library Changes

- On I64 systems, there is no overload of `basic_string` class for type `bool`. Version v3.0 of the Rogue Wave C++ standard library does not have this problematic nonstandard overload. For OpenVMS Alpha, it has been recently removed from the library.
- On I64 systems, class `std::fpos<std::mbstate_t>` does not have the nonstandard member function `offset()`. You can use `fpos::operator streamoff()` instead. For example:

```
#ifndef __USE_STD_Iostream
#define __USE_STD_Iostream
#endif

#include <sstream>

using namespace std;

void foo() {
    istringstream in("hello, world");
    streamoff offset;
    offset = in.tellg().offset(); // Alpha only
    offset = streamoff(in.tellg()); // either Alpha or IPF
}
```

- On OpenVMS Alpha systems, in the default built-in C locale, the monetary facets use values typically found in the `en_US` locale (English in the United States). For example, on Alpha the default national currency string is "\$". On I64 systems, in any locale, including the C locale, the monetary facets use values defined by the locale.

Consider the following sample program:

```
#ifndef __USE_STD_Iostream
#define __USE_STD_Iostream
#endif

#include <iostream>
#include <locale>
#include <stdexcept>
#include <stdlib.h>

#if defined(__osf__) || defined(__vms)
# define UK_LOCALE "en_GB.ISO8859-1"
#elif defined(__linux)
# define UK_LOCALE "en_GB"
#else
# error unknown platform
#endif

using namespace std;
```

Porting to I64 Systems

4.2 Library Changes

```
void outputSym(ostream& os) {
    locale loc = os.getloc();
    const moneypunct<char,false>& mpunct =
        use_facet<moneypunct<char,false> >(loc);
    os << "currency symbol is: " << mpunct.curr_symbol() << endl;
}
```

This program prints two lines: the national currency symbol in the C locale and the national currency symbol in the en_GB locale (English in Great Britain).

```
currency symbol is: $
currency symbol is: £
```

On I64 systems, the output is:

```
currency symbol is:
currency symbol is: £
```

- Consider a program using the C++ Standard Library IOStreams, like `x.cxx` below, that writes to `cout`, but not to `cerr` or `clog`:

```
x.cxx
-----
#ifndef __USE_STD_Iostream
#define __USE_STD_Iostream
#endif
#include <iostream>

main() {
    std::cout << "hello, world" << std::endl;
}
```

On OpenVMS Alpha systems, if such a program is invoked with `SYS$OUTPUT` redirected to a file and `SYS$ERROR` defined as `SYS$OUTPUT`, a single version of the output file is created.

On I64 systems, by default, two versions of the file are created: one for `SYS$OUTPUT` and another for `SYS$ERROR`. To get Alpha behavior on an I64 system, define logical name `DECC$COMMON_STDERR_STDOUT` to `ENABLE`. The following command file shows the definition:

```
x.com
-----
$ if f$search("x.dat") .nes. "" then delete x.dat;*
$ define/user sys$output x.dat
$ define/user sys$error sys$output
$ if f$getsy("arch_name") .eqs. "IA64" then -
    define/user decc$common_stderr_stdout enable
$ run x.exe
```

4.3 CXXLINK Changes

Because of changes in the architecture on I64 systems, CXXLINK plays a much smaller role. Its only remaining purpose is to provide human readable (demangled) names for mangled C++ names in diagnostics generated by the linker.

Specific changes are:

- There is no LIBCXXSTD.OLB
On I64 systems, there is no LIBCXXSTD.OLB, which is the object library where the C++ standard library for OpenVMS Alpha resides. See Section 4.2.4 for more information.
- The library is reorganized
The C++ libraries have been reorganized and incorporated into the base system. CXXLINK no longer needs to specify any C++ libraries when invoking the system linker. See Section 4.2 for more information.
- There are no templates in a repository
With the new template instantiation model, objects are no longer placed in a repository. Therefore, CXXLINK no longer needs to look at the repositories for templates. See Section 4.1.9 for more information.

4.4 Installation

HP C++ is installed using PCSI for OpenVMS I64 systems.

To install HP C++ for OpenVMS I64 systems, set the default directory to a writeable directory to allow the IVP to succeed. Then run the PRODUCT INSTALL command, pointing to the kit location. For example:

```
$ SET DEFAULT SYS$MANAGER  
$ PRODUCT INSTALL CXX/SOURCE=node::device:[kit_dir]
```

After installation, the C++ release notes will be available at:

SYS\$HELP:CXX.RELEASE_NOTES

SYS\$HELP:CXX_RELEASE_NOTES.PS

Here is a sample installation log:

Porting to I64 Systems

4.4 Installation

```
$ PRODUCT INSTALL CXX/SOURCE=NODE1$::DEV1$:[I64_CPP_KIT]
The following product has been selected:
  HP I64VMS CXX T7.0-9          Layered Product [Installed]

Using Templates

A C++ **template** is a framework for defining a set of classes or functions. The process of **instantiation** creates a particular class or function of the set by resolving the C++ template with a group of arguments that are themselves types or values. For example:

```
template <class T> class Array {
    T *data;
    int size;
public:
    T &operator[] (int);
    /* ... */
};
```

The code in this example declares a C++ class template named `Array` that has two data members named `data` and `size` and one subscript operator member function. `Array<int>` instantiates `Array` with type `int`. This instantiation generates the following class definition:

```
class Array {
    int *data;
    int size;
public:
    int &operator[] (int);
    /* ... */
};
```

The compiler supports instantiation of C++ class, function, and static data member templates. The following sections describe using templates with Version 6.0 compilers or later. To understand the differences between the current compiler and Version 5.*n* and to migrate from Version 5.*n* to current compilers, see the appendix on migrating from 5.*n* compilers.

Using Templates

5.1 Template Instantiation Model

5.1 Template Instantiation Model

For every template used in a C++ program, the compiler must create an instantiation for that template. How the compiler does this is referred to as the **template instantiation model**. The template instantiation models differ on the why, what, when, where, and how a template is instantiated. The following outline gives a framework to compare the different models.

1. Why

A template can be instantiated **implicitly** when it is used, **manually** by specific request, or both.

2. What (part of the template is instantiated)

For a template class, each member of the template can be instantiated separately, or if one member is instantiated then all members are instantiated.

3. When

Instantiation can occur at compile time or link time. Version 6.0 or later compilers support only compile-time instantiation.

4. Where

Templates can be instantiated in the object in which they are referenced or in separate objects that are stored in a repository.

5. How

Templates can be instantiated with different linkages. They can be local, global, or **COMDAT** (I64 only). A COMDAT is like a weak global definition, but in addition to permitting duplicate definitions, the linker attempts to eliminate all of the duplicates, saving space in the image.

The numbers in the preceding list are used in subsequent paragraphs to indicate which aspect of the template instantiation model framework is being referenced.

For complex systems, choosing a template instantiation model is a space, time, and build-complexity issue that can be considered for optimizing build speed and reducing program size. The default model, referred to as **automatic template instantiation**, is standard-compliant and should work transparently for most users. HP recommends this model.

Automatic template instantiation:

- Instantiates templates when they are used (1),
- Instantiates only the pieces of a class that are used (2), and

Using Templates

5.1 Template Instantiation Model

- Occurs at compile time (3).

Template instantiation on Alpha and I64 systems differ on the where and the how:

- On Alpha systems, templates are instantiated in a repository (4) using global linkage (5)
- On I64 systems, templates are instantiated in the objects that refer to them (4) as COMDATs (5).

The compiler, CXXLINK, and linker all work together to assure that all templates used in a program are instantiated and transparently linked into the final image.

Even when using automatic template instantiation, manual instantiation (1) is also permitted. When using the default model, manually instantiated templates are placed in the object where the manual instantiation occurs (4). On Alpha systems, they have global linkage; on I64 systems, they are COMDATs (5).

See Table 5–1 for a summary of each template instantiation model's What, Where, and How for both implicit and manual instantiation (the "Why").

5.2 Manual Template Instantiation

The compiler provides the following methods to instantiate templates manually:

- Using the `#pragma` preprocessor directives.
Using an instantiation pragma to direct the compiler to instantiate a specific template, as described in Section 5.2.2.
- Using explicit template instantiation syntax.
The C++ language now defines specific syntax for specifying that a template should be instantiated. See *The C++ Programming Language, 3rd Edition*.
HP strongly recommends using the explicit template instantiation syntax when possible.
- Using the command-line qualifier method.
This method directs the compiler to instantiate templates at compile time in the user's object file. Several qualifiers are available to control linkage and extent of template instantiation. For more information about these qualifiers, see Section 5.2.3.

Using Templates

5.2 Manual Template Instantiation

5.2.1 Mixing Automatic and Manual Instantiation

Object files that have been compiled using manual instantiation can be linked freely with objects that have been compiled using automatic instantiation. To ensure that the template instantiations needed by the files compiled with automatic instantiation are provided, the application must be linked using automatic instantiation, and the appropriate repositories must be present.

When a template instantiation is present in an explicitly named object file or object library it takes precedence over the same named instantiation in a repository.

5.2.2 Instantiation Directives

The next sections describe the following instantiation directives:

```
#pragma define_template  
#pragma instantiate_template  
#pragma do_not_instantiate_template
```

5.2.2.1 #pragma define_template

The compiler provides a mechanism for manual instantiation, using the #pragma define_template directive. This directive lets you tell the compiler what class or function template to instantiate in conjunction with the actual arguments with which the template is to be instantiated. The #pragma define_template directive has the following format:

```
#pragma define_template identifier <template_arguments>
```

Identifier is the name of the class or function template that the compiler is directed to instantiate at compile time. For the instantiation to succeed, the definition of the template must appear before the #pragma define_template directive.

Template arguments is a list of one or more actual types that correspond to the template parameters for the particular class or function template being instantiated. Whatever type is specified is used as the type for the instantiation.

The following is an example of a valid template manual instantiation:

```
//main.cxx  
#include <stdlib.h>  
template <class T> void sort (T*);  
  
int a1[100];  
float a2[100];
```

Using Templates

5.2 Manual Template Instantiation

```
int main()
{
    sort(a1);
    sort(a2);
    return EXIT_SUCCESS;
}

//sort.cxx
template <class T> void sort (T *array)
{
    /* body of sort */
}

#pragma define_template sort<int>
#pragma define_template sort<float>
```

To compile and link these sources, enter the following command:

```
CXXLINK main.cxx,sort.cxx /TEMPLATE_DEFINE=(NOAUTO)
```

When you use `#pragma define_template` or explicit instantiation, only the specified template is instantiated; templates to which it refers because of member types or base classes are not instantiated.

Sorting an array of template class elements requires the use of additional pragmas for the module `sort.cxx`. For example:

```
template <class T> void sort (T* array)
{
    /*body of sort*/
}

template <class T> class entity {
public:
    T member;
    int operator < (const entity<T> &) const;
}

template <class T>
int entity<T>::operator < (const entity<T> &operand) const
{
    return member < operand.member;
}

int a1[100];
float a2[100];
entity<int> a3[100];

#pragma define_template sort<int>
#pragma define_template sort<float>
#pragma define_template sort<entity<int> >
```

Using Templates

5.2 Manual Template Instantiation

```
void sort_all_arrays ()
{
    sort(a1);
    sort(a2);
    sort(a3);
}
```

The `define_template` pragma is position sensitive. If a `define_template` occurs lexically before a function, member function, or static data member template definition, the compiler is unable to instantiate the corresponding template because the body of that template is not present before the pragma directive.

The compiler instantiates all instances of `sort` and of `entity::operator <` needed for this compilation unit.

To organize a program to use the `define_template` pragma, you can place the declarations of class and functions templates into header files, and instantiate all instances of a particular template from a single compilation unit. The following example shows how to do this:

```
// sort.h
#include <stdlib.h>
template <class T> void sort (T*);

// entity.h
template <class T> class entity {
public:
    T member;
    int operator < (const entity<T> &) const;
};

// main.cxx
#include "sort.h"
#include "entity.h"

int a1[100];
float a2[100];
entity<int> a3[100];

int main()
{
    sort(a1);
    sort(a2);
    sort(a3);
    return EXIT_SUCCESS;
}
```

Using Templates

5.2 Manual Template Instantiation

```
// sort.cxx
#include "sort.h"
#include "entity.h"
template <class T> void sort (T* array)
{
    /*body of sort*/
}
#pragma define_template sort<int>
#pragma define_template sort<float>
#pragma define_template sort<entity<int> >
```

Compiling the following file provides a definition of `entity::operator <` with type `int`:

```
// entity.cxx
#include "entity.h"

template <class T>
int entity<T>::operator < (const entity<T> &operand) const
{
    return member < operand.member;
}

#pragma define_template entity<int>
```

To compile this example, issue the following command:

```
cxxlink main.cxx,sort.cxx,entity.cxx
```

If the program uses other instantiations of `entity` in other compilation units, you can provide definitions of `operator <` for those entities by adding `define_template` pragmas to `entity.cxx`. For example, if other compilation units use the following instantiations of `entity`, appending the following pragmas to `entity.cxx` causes the compiler to generate instantiations of `operator <` for those requests of `entity`:

```
entity<long> and entity< entity<int> >,
#pragma define_template entity<long>
#pragma define_template entity< entity<int> >
```

Like any other pragma, the `#pragma define_template` pragma must appear on a single line. Pragmas may be continued on multiple lines by escaping the end of line with a backslash (`\`) as with other preprocessor statements.

Using Templates

5.2 Manual Template Instantiation

5.2.2.2 #pragma instantiate and #pragma do_not_instantiate

The compiler also provides several pragmas that provide fine control over the instantiation process. Instantiation pragmas, for example, can be used to control the instantiation of specific template entities or sets of template entities. There are two instantiation pragmas:

- The `instantiate` pragma causes a specified entity to be instantiated, similar to the `define_template` pragma. It provides finer instantiation control than `define_template` when instantiating function templates.
- The `do_not_instantiate` pragma suppresses the instantiation of a specified entity. It is typically used to suppress the instantiation of an entity for which a specific definition is supplied.

The argument to the instantiation pragma can be:

a template class name	<code>A<int></code>
a template class declaration	<code>class A<int></code>
a member function name	<code>A<int>::f</code>
a static data member name	<code>A<int>::i</code>
a static data declaration	<code>A<int>::i</code>
a member function declaration	<code>void A<int>::f(int, char)</code>
a template function declaration	<code>char* f(int, float)</code>

A pragma in which the argument is a template class name (for example, `A<int>` or `class A<int>`) is equivalent to repeating the pragma for each member function and static data member declared in the class. When instantiating an entire class, a given member function or static data member may be excluded using the `do_not_instantiate` pragma. For example:

```
#pragma instantiate A<int>
#pragma do_not_instantiate A<int>::f
```

The template definition of a template entity must be present in the compilation for an instantiation to occur. If an instantiation is explicitly requested by use of the `instantiate` pragma and no template definition is available or a specific definition is provided, an error is issued.

Using Templates

5.2 Manual Template Instantiation

```
template <class T> void f1(T); // No body provided
template <class T> void g1(T); // No body provided
void f1(int) {} // Specific definition
#include <stdlib.h>
int main()
{
    int    i;
    double d;
    f1(i);
    f1(d);
    g1(i);
    g1(d);
    return EXIT_SUCCESS;
}
#pragma instantiate void f1(int) // error - specific definition
#pragma instantiate void g1(int) // error - no body provided
```

The functions `f1(double)` and `g1(double)` are not instantiated (because no bodies were supplied) but no errors are produced during the compilation (if no bodies are supplied at link time, a linker error is produced).

A member function name (for example, `A<int>::f`) can be used as a pragma argument only if it refers to a single user-defined member function (that is, not an overloaded function). Compiler-generated functions are not considered, so a name may refer to a user-defined constructor even if a compiler-generated copy constructor of the same name exists. Overloaded member functions can be instantiated by providing the complete member function declaration:

```
#pragma instantiate char* A<int>::f(int, char*)
```

The argument to an instantiation pragma must not be a compiler-generated function, an inline function, or a pure virtual function.

5.2.3 Using Command Qualifiers for Manual Instantiation

Alternatively, you could use the `/TEMPLATE_DEFINE` qualifier to instantiate templates manually.

Considering the previous examples in this section, you can use this qualifier to supply definitions of `sort<int>`, `sort<float>`, and `sort<entity><int>` by compiling the following file using `/TEMPLATE_DEFINE=ALL`:

```
// sort.cxx
#include "sort.h"
#include "entity.h"

template <class T>
static sort (T* array)
{
    /*body of sort*/
}
```

Using Templates

5.2 Manual Template Instantiation

```
static void function_never_used ()
{
    int a1[100];
    float a2[100];
    entity<int> a3[100];

    sort(a1);
    sort(a2);
    sort(a3);
}
```

You can use the `/TEMPLATE_DEFINE=USED` and `/TEMPLATE_DEFINE=LOCAL` qualifiers for manual template instantiation. The `/TEMPLATE_DEFINE=USED` qualifier acts like `/TEMPLATE_DEFINE=ALL`, except that only those template instantiations that are referenced in the source file are actually instantiated. The `/TEMPLATE_DEFINE=LOCAL` qualifier acts like `/TEMPLATE_DEFINE=USED`, except that the templates are instantiated with internal linkage. This provides a simple way to build applications but creates executables that are larger than necessary. It also fails if the template classes being instantiated have static data members.

You can use the `/TEMPLATE_DEFINE=ALL_REPOSITORY`, `/TEMPLATE_DEFINE=USED_REPOSITORY`, and `/TEMPLATE_DEFINE=IMPLICIT_LOCAL` qualifiers to create preinstantiation libraries. See Section 5.6.

5.3 Using Template Object Repositories *(Alpha only)*

In automatic template instantiation mode, the compiler attempts to instantiate every referenced template at compile time. For automatic instantiation to work, at least one compilation that references a template function must be able to find the template definition. There is no restriction on where a template can be declared or defined, as long as the definition is visible to the compilation unit. You can use implicit inclusion to find it.

The compiler writes instantiation object files to a directory called the repository; file names are based on the names of the entities being instantiated. The default repository is `[.cxx_repository]`.

5.3.1 Specifying Alternate Repositories

You can use the `/REPOSITORY` command-line qualifier to specify one or more alternate repository directories. The first repository named is the read-write repository into which the compiler writes instantiation objects when processing. At link time, all repositories are read only. There is one object file in the repository for each instantiated template function, for each instantiated static data member, and for each virtual table required for virtual functions.

Using Templates

5.3 Using Template Object Repositories *(Alpha only)*

When the program is linked, the linker searches the repositories for needed template instantiations.

5.3.2 Reducing Compilation Time with the `/TEMPLATE_DEFINE=TIMESTAMP` Qualifier

To keep instantiations up to date, the compiler always instantiates templates by default, even if the required template already exists in the repository. However, in environments that share many templates among many sources, this process can increase compilation time.

In these environments, users can specify the `/TEMPLATE_DEFINE=TIMESTAMP` qualifier to override the default behavior and thereby reduce compilation time. This qualifier causes the compiler to create a timestamp file named `TIMESTAMP.` in the repository. Thereafter, instantiations are added or regenerated only if needed; that is, if they do not already exist, or if existing ones are older than the timestamp.

The `/TEMPLATE_DEFINE=TIMESTAMP` qualifier is immediately useful when building a system from scratch, starting with an empty repository. It avoids reinstantiating unchanged code and is totally safe, because all required instantiations are generated and up to date.

Incremental application building is normally done without this qualifier, so that new instantiations overwrite earlier ones as sources are recompiled.

Although the `/TEMPLATE_DEFINE=TIMESTAMP` qualifier is intended mainly for initial builds, you can use it for ongoing development in a structured way. Because the compiler creates a new timestamp file only if one does not already exist, you must remove or modify any existing timestamp file before making changes to your code base. This procedure ensures that all subsequent compilations generate up-to-date instantiations.

In the following example, the file is removed before and immediately after the compilation of `a.cxx`, `b.cxx`, and `c.cxx`.

```
$ DELETE [.cxx_repository]TIMESTAMP.*
$ CXX /TEMPLATE_DEFINE=TIMESTAMP a.cxx
$ CXX /TEMPLATE_DEFINE=TIMESTAMP b.cxx
$ CXX /TEMPLATE_DEFINE=TIMESTAMP c.cxx
$ DELETE [.cxx_repository]TIMESTAMP.*
```

All instantiations needed by `a.cxx`, `b.cxx`, and `c.cxx` are generated only once, as opposed to the default scheme, in which they would be generated three times if all three modules used the instantiations.

Using Templates

5.3 Using Template Object Repositories *(Alpha only)*

Specifying the `/TEMPLATE_DEFINE=VERBOSE` qualifier causes the compiler to emit an informational message naming the instantiation and repository file being skipped in this mode.

5.3.3 Compiling Programs with Automatic Instantiation

In general, the use of automatic template instantiation is transparent to the user. Automatic template instantiation is enabled by default. The following commands are equivalent:

```
CXX file.cxx
CXX/TEMPLATE_DEFINE=(AUTO,PRAGMA) file.cxx
CXX/REPOSITORY=[.CXX_REPOSITORY] file.cxx
```

These commands:

- Cause the compilation of the file `file.cxx`
- Create any instantiations that are required whose definitions are visible to the compiler
- Create an executable, `a.out`, by linking together the generated object file and any instantiations required from the repository

You can specify the repository explicitly with the `/REPOSITORY` qualifier. For example:

```
CXX /REPOSITORY=C$:[PROJECT.REPOSITORY] file.cxx
```

This command compiles `file.cxx`, produces an object file in the current directory, and puts instantiated template files in the directory `C$:[PROJECT.REPOSITORY]`.

You can specify multiple directories using the `/REPOSITORY` qualifier. The first named repository is denoted as the read/write repository. The compiler writes instantiation files to this repository. The other repositories are denoted as read only repositories. They are searched by the link command as described in Section 5.3.4.

The compiler attempts to instantiate templates at compile time; therefore, any specialization used in the program must be declared in each file in which the specialization is referenced, to prevent the instantiation of the overridden template function.

If a template instantiation refers to a static function, that function is created as an external entry point in the primary object file, and the instantiation object file in the repository then refers to this `__STF` function.

Using Templates

5.3 Using Template Object Repositories *(Alpha only)*

If the template instantiation is linked into an application that does not have the original primary object file, an unresolved reference to the `__STF` function occurs. If this happens, recompile an object file that regenerates the instantiation or use manual instantiation to reinstantiate the template.

5.3.4 Linking Programs with Automatic Instantiation

When compiling and linking an application, you must use the same repositories in both the compilation and link steps.

If you name a repository explicitly in the compile step, you must also name it in the link step. For example:

```
CXX /REPOSITORY=[.MY_REPOSITORY] a.cxx,b.cxx
CXXLINK /REPOSITORY=[.MY_REPOSITORY] a.obj b.obj
```

If you use different repositories the compilation of the sources, you must specify all of them on the link step:

```
CXX /REPOSITORY=[.REPOSITORY1] a.cxx
CXX /REPOSITORY=[.REPOSITORY2] b.cxx
CXXLINK /REPOSITORY=( [.REPOSITORY1], [.REPOSITORY2]) a.obj b.obj
```

At link time, the specified repositories are searched in the order given, to find the required instantiations. If you use several repositories, and if one of them is the default, you must specify all repositories on the link step:

```
CXX a.cxx
CXX /REPOSITORY=[.REPOSITORY2] b.cxx
CXX /REPOSITORY=( [.CXX_REPOSITORY], [.REPOSITORY2]) a.obj b.obj
```

It is usually much easier and safer to use a single repository, because the same instantiations could potentially be present in multiple repositories, and it is possible to update some but not all repositories when changes are made to templates.

The CXXLINK step processes object files so that all the external symbol references are resolved. The objects are linked together in the following order:

1. The order in which object files and object libraries are specified on the command line.
2. If `/NOTEMPLATE_PRELINK` is specified, stop.
3. For each unresolved external, search the repositories in the order specified on the command line for a file that contains that external. If such a file is found, add it at the top of the list of object files being searched.
4. Link again and repeat Step 3 until no more externals are found or until no more object files are found in which to resolve the external.

Using Templates

5.3 Using Template Object Repositories *(Alpha only)*

Note the following:

- Instantiations that appear in explicitly linked object files or libraries hide instantiations in the repositories.
- Only template instantiations that are actually referenced in sources that can instantiate them appear in the repository. You must specify any other instantiations manually or use the `/TEMPLATE_DEFINE=ALL_REPOSITORY` qualifier.
- Instantiations are satisfied from the list of unsatisfied externals from the linking of specified files, but are linked at the beginning of those files. This means that they are linked in only if they are satisfied from no specified file, given the linker's file order behavior, and if they bring in any external references they need from the first library that satisfies them.

5.3.5 Creating Libraries

Creating libraries with object files created with automatic instantiations is relatively straightforward. You must decide where the instantiations that were generated automatically are provided to the users of the library. For applications that use the library to link successfully, all template instantiations that are needed by the code in the library must be available at link time. This can be done in two ways:

- Put the instantiations in the library. They hide the same named instantiations in any repositories or any libraries following the library on the command line.
- Provide a repository that contains the instantiations.

It is usually easiest to put the instantiations in the library. This is a good choice if the instantiations are internal to the library and are not instantiated directly by the user's code. To put the instantiations in the library, add all of the object files in the repositories required by the library into the library as shown in the following example:

```
CXX /REPOSITORY=[.lib_repository] a.cxx,b.cxx,c.cxx
LIBRARY/CREATE/OBJECT mylib
LIBRARY/INSERT/OBJECT mylib a.obj,b.obj,c.obj
LIBRARY/INSERT/OBJECT mylib [lib_repository]*.OBJ
```

If the template instantiations can be overridden by the user, the templates should be provided in a repository that the user specifies after all the user's repositories. For the previous example, create the library as follows:

```
CXX /REPOSITORY=[.lib_repository] a.cxx,b.cxx,c.cxx
LIBRARY/CREATE/OBJECT mylib
LIBRARY/INSERT/OBJECT mylib a.obj,b.obj,c.obj
```

Using Templates

5.3 Using Template Object Repositories *(Alpha only)*

When linking the application, enter the CXXLINK command as follows:

```
CXXLINK user_code.obj,mylib/LIB
```

If some objects from [.lib_repository] are not contained in mylib.olb, specify [.lib_repository] as the last read-only repository on the line follows:

```
CXXLINK /REPOSITORY=( [.cxx_repository] , [.lib_repository] )
        user_code.obj,mylib/LIB
```

You must explicitly name the repository when linking, even if it is the default repository [.cxx_repository]; cxx first satisfies all unresolved instantiations from [.cxx_repository], and uses [.lib_repository] to resolve any remaining unresolved instantiations.

Only the instantiations that are required by the code in the library are generated in the library repository lib_repository. If you must provide other instantiations that you require but cannot instantiate, you must provide these instantiations using manual template instantiation or by specifying the qualifier /TEMPLATE_DEFINE=ALL_REPOSITORY.

5.3.6 Multiple Repositories

As shown in Section 5.5.3, multiple repositories can be specified to link an application. The first repository named is the read-write repository, and when compiling, the compiler writes instantiation object files into it. At link time, all repositories are read only.

The repositories are searched in a linear order, iteratively, and satisfy only the unresolved instantiations from each pass. That is, references from instantiations that are added in one pass are not resolved until the next pass. Consider the link line in the previous example:

```
mylib.olb
```

In this example, all references that could be resolved from lib_repository would be resolved in the first pass. Any reference arising from an instantiation in lib_repository in the first pass would be resolved by instantiations in [.cxx_repository] in the second pass.

5.4 Using COMDATS *(164 only)*

The primary purpose of a template repository is to guarantee that only one copy of a template instantiation is included in a program. Another way to achieve this is to use COMDATs. COMDATs are special symbols that are globally visible; however, when the linker encounters a duplicate definition, it is removed. This allows the compiler to define templates directly in every object module that uses them.

Using Templates

5.4 Using COMDATS *(I64 only)*

The principal benefit of using COMDATS is build speed, but it also can simplify the build procedure:

- Compilation speed is improved because writing template instantiations into the current object is significantly faster than writing them into the repository, because of object overhead in the latter case.
- Link speed is improved because determining which templates to include from the template repository requires multiple passes of the linker.
- The build is simplified by eliminating the need to manage the template repository and explicitly extract objects.

COMDATs are implemented on I64 systems using ELF group sections. COMDATs are not implemented on Alpha systems because EOBJ does not support them. If EOBJ supported COMDATs, then they also would have been used on Alpha systems instead of the template object repository. Currently, there are no plans to implement COMDATs on Alpha systems.

Because templates instantiated using COMDATs exist in the same object where they are used, there are no special procedures for linking programs or creating libraries, except that a template can only be exported from a single shared library. If two shared libraries with the same exported template are linked together, a MULDEF will occur. This restriction also exists on Alpha systems.

5.5 Advanced Program Development and Templates

The following sections discuss templates in the context of advanced program development.

5.5.1 Implicit Inclusion

When implicit inclusion is enabled, the compiler assumes that if it needs a definition to instantiate a template entity declared in a `.h` or `.hxx` file, it can implicitly include the corresponding implementation file to obtain the source code for the definition.

If a template entity `ABC::f` is declared in file `xyz.h`, and an instantiation of `ABC::f` is required in a compilation but no definition of `ABC::f` appears in the source code, the compiler checks whether a file `xyz.cxx` exists. If it does, the compiler processes it as if it were included at the end of the main source file.

When looking for a template definition, the compiler uses the following lookup order:

Using Templates

5.5 Advanced Program Development and Templates

1. If the `#include` name for the header file containing the template declaration is specified with an absolute path name, look only in the directory specified by the path name.
2. If the `#include` for the header file containing the template declaration is specified with a relative path name, take the following action:
 - If the header file name is specified with double quotation marks (" ") and the `/NOCURRENT_INCLUDE` qualifier was not specified, append the relative path name to the directory containing the source file and search for files with the appropriate suffixes.
 - Otherwise, append the relative path name to all the `-I` directories and look in those resulting directories for files with the appropriate suffixes.

Note

A place containing a forward slash (/) character is considered to be a UNIX-style name. If the name in the `#include` directive also contains a "/" character that is not the first character and is not preceded by an exclamation mark character (!) (that is, it is not an absolute UNIX-style pathname), the name in the `#include` directive is appended to the named place, separated by a "/" character, before applying the `decc$to_vms` pathname translation function.

For source files, the appropriate suffixes are, in order of preference: `.CXX`, `.C`, `.CC`, and `.CPP` or as defined by the `/TEMPLATE_DEFINE=DEFINITION_FILE_TYPE` qualifier.

The compiler ignores any file extension that does not begin with a dot (.

The `/TEMPLATE_DEFINE=DEFINITION_FILE_TYPE` qualifier allows the user to define explicitly the file extensions to be used with implicit inclusion. For example:

```
CXX file.cxx /TEMPLATE_DEFINE=DEF=".CPP.CC"
```

This command searches for template definition files with the extensions `.CPP` and `.CC`.

Using Templates

5.5 Advanced Program Development and Templates

5.5.2 Dependency Management

The compiler does no dependency management of its own. Because template instantiations are compiled when source files that reference those instantiations are compiled, those source files must be recompiled if the template declaration or definition changes.

The /MMS output from the compiler lists the implicitly included files, so that the MMS program can automatically recompile any source files that depend upon template files. If MMS is not being used, it is the user's responsibility to ensure that instantiations that have changed are recompiled. The user does so by recompiling at least one source file that references the changed instantiations.

The compiler does not check command line dependencies of template instantiations at link time. If you compile two different source files that instantiate a specific template with two different sets of qualifiers, the behavior is undefined. Use consistent qualifier settings for each build into each repository. Examples of qualifier settings that could cause unexpected results are as follows:

- /STANDARD=STRICT_ANSI. Use of guiding declarations is not allowed, and some templates might not be instantiated as they would be in other modes.
- /DEBUG. Debug information is generated for some instantiations and not for others. Be sure that is what you want.
- /NOMEMBER_ALIGNMENT. Some instantiations with this setting assume that classes have unaligned members; instantiations generated by compiling files with the default setting do not.

5.5.3 Creating a Common Instantiation Library

Because the automatic instantiation model has changed to a compile time model with Version 6.0, (see Sections 5.3.3 and 5.3.4), the procedure used to create a common instantiation library has also changed. This section describes the new procedure.

If you want to put all current instantiations into a common instantiation library, follow these steps:

1. Compile with the /TEMPLATE=VERBOSE qualifier and save the results to a file.
2. Edit that file and save the names that appear after the "automatically instantiating ..." string. You can ignore any messages about instantiating vtables. Put #pragma instantiate before each name.

Using Templates

5.5 Advanced Program Development and Templates

3. Put the result of that edit into a separate source file and include at the top of the file any headers needed for template definitions.
4. Put matching `#pragma do_not_instantiate` (see Section 5.2.2.2) into the headers that define each of these template classes or functions.
5. Place each `#pragma do_not_instantiate` directive between an `#ifndef` of the form `#ifndef SOME_MACRO_NAME` and an `#endif`.
6. Compile the `inst.cxx` file with `SOME_MACRO_NAME` defined.
7. Link the source file with the resulting object file.

The following examples show how to create a common instantiation library for all the instantiations currently being automatically instantiated for this file.

```
// foo.cxx
#include <stdlib.h>
#include <vector>
#include "C.h"

int main() {
    vector<C> v;
    v.resize(20);
    return EXIT_SUCCESS;
}

// C.h
#ifndef __C_H
class C {};
#endif
```

Compiling with the `/TEMPLATE=VERBOSE` qualifier shows which instantiations occur automatically:

```
void vector<T,Allocator>::resize (size_type new_size)
.....^
% CXX-I-INSTENTITY, automatically instantiating void std::vector<C,
std::allocator<C > >::resize(unsigned int)
at line number 90 in module VECTOR.CC of text library SYS$COMMON:[SYSLIB]CXXL$ANSI_DEF.TLB;4
//
```

1. Place all these instantiations into a file called `inst.cxx` that is built separately or into a library:

```
// inst.cxx
#include <vector>
#include "C.h"
```

Using Templates

5.5 Advanced Program Development and Templates

```
#pragma instantiate void std::vector<C, std::allocator<C >
>::resize(unsigned long)
#pragma instantiate void std::vector<C, std::allocator<C >
>::insert(C *, unsigned long, const C &)
#pragma instantiate void std::vector<C, std::allocator<C >
>::__insert(C *, unsigned long, const C &, __true_category)
#pragma instantiate C *std::copy_backward(C *, C *, C *)
#pragma instantiate void std::fill(C *, C *, const C &)
#pragma instantiate C *std::copy(C *, C *, C *)
#pragma instantiate const unsigned long std::basic_string<char,
std::char_traits<char >, std::allocator<void> >::npos
```

2. Add these instantiations into C.h and change “instantiate” to “do_not_instantiate”. Add an #ifndef, so that when building inst.cxx, the compiler creates these instantiations in the inst object file:

```
#ifndef __C_H
class C {};

#ifdef __BUILDING_INSTANTIATIONS
#pragma do_not_instantiate void std::vector<C, std::allocator<C >
>::resize(unsigned long)
#pragma do_not_instantiate void std::vector<C, std::allocator<C >
>::insert(C *, unsigned long, const C &)
#pragma do_not_instantiate void std::vector<C, std::allocator<C >
>::__insert(C *, unsigned long, const C &, __true_category)
#pragma do_not_instantiate C *std::copy_backward(C *, C *, C *)
#pragma do_not_instantiate void std::fill(C *, C *, const C &)
#pragma do_not_instantiate C *std::copy(C *, C *, C *)
#pragma do_not_instantiate const unsigned long
std::basic_string<char, std::char_traits<char >,
std::allocator<void> >::npos
#endif
#endif
```

3. Build the inst object file:

```
CXX/DEFINE=BUILDING_INSTANTIATIONS inst.cxx
```

4. Link with the inst object file. It will use instantiations from that file instead of creating them automatically:

```
cxx foo.cxx
cxxlink foo inst
```

To verify that your procedure worked correctly, you can remove all files from the cxx_repository subdirectory before you compile foo.cxx. This subdirectory should contain no instantiations after linking with the inst object file.

5.5 Advanced Program Development and Templates

If you have an `inst.cxx` file that contains many instantiations and you do not want all the symbols in the `inst` object file to be put into a user's executable even if only some symbols are used, (as happens with archive libraries), you can either split the `inst.cxx` into many smaller source files, or specify the `/DEFINE_TEMPLATE=USED_REPOSITORY` qualifier to create the instantiations as separate object files in the repository (see Section 5.6). You must then link all the required individual object files in the repository into your library.

5.6 Command-Line Qualifiers for Template Instantiation

This section describes the C++ command-line qualifiers that specify the template instantiation model, and additional template-related qualifiers.

5.6.1 Instantiation Model Qualifiers

The following CXX command-line qualifiers specify the template instantiation model to be used. Specify only one:

`/TEMPLATE_DEFINE=ALL`

Instantiate all template entities declared or referenced in the compilation unit, including typedefs. For each fully instantiated template class, all its member functions and static data members are instantiated even if they were not used. Nonmember template functions are instantiated even if the only reference was a declaration. Instantiations are created with external linkage. Overrides `/REPOSITORY` at compile time. Instantiations are placed in the user's object file.

`/TEMPLATE_DEFINE=ALL_REPOSITORY`

Instantiate all templates declared or used in the source program and put the object code generated as separate object files in the repository. Instantiations caused by manual instantiation directives are also put in the repository. This is similar to `/TEMPLATE_DEFINE=ALL` except that explicit instantiations are also put in the repository, rather than an external symbol being put in the main object file. This qualifier is useful for creating a pre-instantiation library.

`/TEMPLATE_DEFINE=[NO]AUTOMATIC`

`/TEMPLATE_DEFINE=AUTOMATIC` directs the compiler to use the automatic instantiation model of C++ templates.

`/TEMPLATE_DEFINE=NOAUTOMATIC` directs the compiler to not implicitly instantiate templates.

`/TEMPLATE_DEFINE=AUTOMATIC` is the default.

Using Templates

5.6 Command-Line Qualifiers for Template Instantiation

/TEMPLATE_DEFINE=IMPLICIT_LOCAL

Same as `template_define=-local`, except manually instantiated templates are placed in the repository with external linkage. This is useful for build systems that need to have explicit control of the template instantiation mechanism. This mode can suffer the same limitations as `template_define=-local`. This mode is the default when `-std gnu` is specified.

/TEMPLATE_DEFINE=LOCAL

Similar to `/TEMPLATE_DEFINE=USED` except that the functions are given internal linkage. This qualifier provides a simple mechanism for getting started with templates. The compiler instantiates as local functions the functions used in each compilation unit, and the program links and runs correctly (barring problems resulting from multiple copies of local static variables). However, because many copies of the instantiated functions can be generated, this qualifier might not be suitable for production use.

The `/TEMPLATE_DEFINE=LOCAL` qualifier cannot be used in conjunction with automatic template instantiation. If automatic instantiation is enabled by default, it is disabled by the `/TEMPLATE_DEFINE=LOCAL` qualifier. Explicit use of `/TEMPLATE_DEFINE=LOCAL` and `/PT` is an error.

/TEMPLATE_DEFINE=USED

Instantiate those template entities that were used in the compilation. This includes all static data members for which there are template definitions. Overrides `/PT` at compile time.

/TEMPLATE_DEFINE=USED_REPOSITORY

Like `/TEMPLATE_DEFINE=ALL_REPOSITORY`, but instantiates only templates used by the compilation. The explicit instantiations are also put into the repository as separate object files.

Table 5–1 summarizes each template instantiation model's What, Where, and How (as described in Section 5.1) for both implicit and manual instantiation.

Using Templates

5.6 Command-Line Qualifiers for Template Instantiation

Table 5–1 Template Instantiation Models

Model (/TEMPLATE=)	Why					
	Implicit			Manual		
	What	Where	How	What	Where	How
AUTO	part	repository for Alpha, object for I64	global for Alpha, COMDAT for I64	part	object	global for Alpha, COMDAT for I64
NOAUTO	N/A	N/A	N/A	part	object	global for Alpha, COMDAT for I64
IMPLICIT_LOCAL	part	object	local for Alpha, COMDAT for I64	part	object	global for Alpha, COMDAT for I64
LOCAL	part	object	local for Alpha, COMDAT for I64	part	object	local for Alpha, COMDAT for I64
USED	part	object	global for Alpha, COMDAT for I64	part	object	global for Alpha, COMDAT for I64
USED_REPO	part	repository	global for Alpha, COMDAT for I64	part	repository	global for Alpha, COMDAT for I64
ALL	all	object	global for Alpha, COMDAT for I64	all	object	global for Alpha, COMDAT for I64
ALL_REPO	all	repository for Alpha, object for I64	global for Alpha, COMDAT for I64	all	repository for Alpha, object for I64	global for Alpha, COMDAT for I64

5.6.2 Other Instantiation Qualifiers

The following qualifiers are independent of the model used and each other:

/TEMPLATE_DEFINE=DEFINITION_FILE_TYPE="file-type-list"

Specifies a string that contains a list of file types that are valid for template definition files. Items in the list must be separated by commas and preceded by a period. A type is not allowed to exceed the OpenVMS limit of 31 characters. This qualifier is applicable only when automatic instantiation has been specified. The default is /TEMPLATE_DEFINE=DEF=".CXX,.C,.CC,.CPP".

/TEMPLATE_DEFINE=PRAGMA

Determines whether the compiler ignores #pragma define_template directives encountered during the compilation. This qualifier lets you quickly switch to automatic instantiation without having to remove all the pragma

Using Templates

5.6 Command-Line Qualifiers for Template Instantiation

directives from your program's code base. The default is `/TEMPLATE_DEFINE=PRAGMA`, which enables `#pragma define_template`.

`/TEMPLATE_DEFINE=VERBOSE`

Turns on verbose or verify mode to display each phase of instantiation as it occurs. During the compilation phase, informational level diagnostics are generated to indicate which templates are automatically being instantiated. This qualifier is useful as a debugging aid.

`/PENDING_INSTANTIATIONS[=n]`

Limit the depth of recursive instantiations so that infinite instantiation loops can be detected before some resource is exhausted. The `/PENDING_INSTANTIATIONS` qualifier requires a positive non-zero value *n* as argument and issues an error when *n* instantiations are pending for the same class template. The default value for *n* is 64.

5.6.3 Repository Qualifiers

The following qualifiers are only applicable if a repository is being used (*Alpha only*):

`/TEMPLATE_DEFINE=TIMESTAMP`

Causes the compiler to create a timestamp file named `TIMESTAMP.` in the repository. Thereafter, instantiations are added or regenerated only if needed; that is, if they do not already exist, or if existing ones are older than the timestamp.

`/REPOSITORY`

Specifies a repository that C++ uses to store requested template instantiations. The default is `/REPOSITORY=[.CXX_REPOSITORY]`. If multiple repositories are specified, only the first is considered writable, and the default repository is ignored unless specified.

6

Handling C++ Exceptions

Exception handling is a C++ language mechanism for handling unusual program events (not just errors). On OpenVMS systems, HP C++ implements the exception handling model described in the C++ International Standard.

This includes support for throwing and catching exceptions, and calling the `terminate()` and `unexpected()` functions. C++ exception-handling support is implemented using functions and related OpenVMS systemservices that comprise the OpenVMS condition-handling facility. Hence, C++ exception-handling support is fully integrated with existing uses of the OpenVMS condition handling facility.

6.1 Compiling with Exceptions

Because exceptions are enabled by default, you need not specify the `/EXCEPTIONS` qualifier whenever you compile the program.

For more information about the `/EXCEPTIONS` qualifier see Appendix A.

Note

If you are programming in kernel mode or creating a protected shareable image, C++ exception handling is not supported. To ensure that your code does not contain constructs that trigger C++ exceptions or to prevent errors from occurring during initialization of exception handlers at runtime, specify the `/NOEXCEPTIONS` qualifier when compiling.

Handling C++ Exceptions

6.2 Linking with Exceptions *(Alpha only)*

6.2 Linking with Exceptions *(Alpha only)*

If any files in your program contain throw expressions, try blocks, or catch statements, or if any files in your program are compiled with the exceptions, you must link your program using the `cxxlink` facility (see Section 1.3 for more information on this facility). For example:

```
$ cxxlink my_prog.obj
```

Using the `cxxlink` facility ensures that the run-time support for exceptions (`sys$library:libcxxstd.olb`) is linked into your program.

Linking with `/NOSYSSHR` (OpenVMS Version 6.2)

If you are running OpenVMS Version 6.2 or later, and you want to link using the `/NOSYSSHR` qualifier, you must specify a linker options file on your `cxxlink` command. Otherwise, your link might fail because of undefined symbol references.

The linker options file should contain the following:

```
sys$share:librtl.exe/shar
```

For example, if `cxx_exc.opt` is your linker options file containing the above line, then a possible link command would be:

```
$ cxxlink my_prog.obj, my_disk:[my_dir]cxx_exc.opt/opt
```

Because the necessary run-time libraries are not provided in object format on OpenVMS Version 6.1 and earlier releases, linking with `/NOSYSSHR` on those systems is not recommended.

For more information about linking with `/NOSYSSHR` and about OpenVMS linker options files see the *OpenVMS Linker Utility Manual*

6.3 The `terminate()` and `unexpected()` Functions

The `unexpected()` and `set_unexpected()` functions are implemented as defined in the ISO/IEC International Standard.

The `terminate()` and `set_terminate()` functions are implemented as defined in the ISO/IEC International Standard. By default, the `terminate()` function raises the OpenVMS condition `cxxl$_terminate`, and then calls the `abort()` function.

On Alpha systems, no stack unwinding is done by the `terminate()` function. Hence, no destructors are called for constructed objects when a thrown exception results in a call of the `terminate()` function. Instead, the program is terminated.

Handling C++ Exceptions

6.3 The `terminate()` and `unexpected()` Functions

On I64 systems, stack unwinding *is* done.

If a C++ function is called from a program in which the main function is not C++, `terminate()` is not called. Instead, the call stack points to the point of the throw.

6.4 C++ Exceptions and Other Conditions

Because C++ exceptions are implemented using the OpenVMS condition handling facility, C++ modules will work properly when they are part of a program that makes other uses of OpenVMS condition handling.

The raising and handling of an OpenVMS condition can result in the destruction of C++ automatic objects. If the handling of an OpenVMS condition results in an unwind through a C++ function's stack frame, then destructors will be called for automatic objects declared in that stack frame, just as if a C++ exception had been caught by a handler in an outer stack frame.

The C++ exception handling facility can also be used to catch OpenVMS conditions that are raised independently of C++ throw expressions. Except for those OpenVMS conditions that result in the delivery of signals, a C++ `catch(. . .)` handler will catch both C++ thrown exceptions and OpenVMS conditions. (For more information about OpenVMS conditions that result in the delivery of signals, see Section 6.5.)

You can use the data type `struct chf$signal_array &`, defined in the system header file `chfdef.h`, to catch OpenVMS conditions and to obtain information about the raised conditions. The C++ exceptions support transfers control to `catch(struct chf$signal_array &)` handlers when it determines that an OpenVMS condition was raised independently of a C++ throw statement.

If the `catch (struct chf$signal_array &)` handler specifies a class object, then the C++ exceptions support sets the class object to be a reference to the raised OpenVMS condition's signal argument vector. In the following example, `obj.chf$l_sig_name` will have the value 1022 when it is printed:

Handling C++ Exceptions

6.4 C++ Exceptions and Other Conditions

```
#include <chfdef.h>
#include <iostream.hxx>
#include <lib$routines.h>
main ()
{
    try {
        lib$signal (1022);
    } catch (struct chf$signal_array &obj) {
        cout << obj.chf$_sig_name << endl;
    }
}
```

A `catch(struct chf$signal_array &)` handler will also catch a thrown object that is explicitly declared to be of type `struct chf$signal_array &`. In this case, the value of the catch handler's object is determined by the originally thrown object, not the OpenVMS signal argument vector.

You can also use the data type `struct chf$signal_array *` to catch both OpenVMS conditions and objects explicitly declared to be of type `struct chf$signal_array *`. If a `catch(struct chf$signal_array *)` handler specifies an object, then that object becomes a pointer to the thrown object.

For more information about OpenVMS conditions, see the OpenVMS Calling Standard.

6.5 C++ Exceptions and Signals *(Alpha only)*

Certain OpenVMS conditions (as described in the *HP C Run-Time Library Reference Manual for OpenVMS Systems*) normally result in the delivery of signals. These signals can be processed using the signal handler mechanism described in the *HP C Run-Time Library Reference Manual for OpenVMS Systems*.

You can call the following run-time function in conjunction with the `/EXCEPTION=IMPLICIT` qualifier to cause these OpenVMS conditions to be treated as exceptions, instead of signals:

```
cx1$set_condition(condition_behavior signal_or_exc)
```

This can be done by putting the following call in your program:

```
#include <cxx_exception.h>
...
cx1$set_condition (cxx_exception);
```

Caution

You must specify `/EXCEPTION=IMPLICIT`; otherwise, the code that would normally cause a signal and now causes an exception might be

Handling C++ Exceptions

6.5 C++ Exceptions and Signals *(Alpha only)*

moved out of the try block.

After your program calls the `cxxl$set_condition (cxx_exception)` function you can then catch these exceptions using any of the following handlers:

```
catch(struct chf$signal_array &)  
catch(struct chf$signal_array *)  
catch( . . . )
```

To revert back to the default signal behavior, you can make the following call:

```
cxxl$set_condition (unix_signal);
```

Caution

Avoid doing a C++ throw from a C signal handler or VMS exception handler because this action could terminate your program.

The following are defined in the header file `cxx_exception.h`:

```
The cxxl$set_condition() function  
The condition_behavior {unix_signal=0, cxx_exception=1 }  
enumeration type
```

The `cxxl$set_condition` function returns the previous setting. This function affects all threads in a process.

6.6 C++ Exceptions with `setjmp` and `longjmp`

If a C++ function calls either the `setjmp()` or the `longjmp()` routine, C++ exceptions support is disabled for that function. This means the following:

- No exceptions can be caught by the function's catch handlers.
- No destructors are called for the function's automatic data if an exception propagates through the function.
- The `unexpected()` function is not called for that function.
- If either `setjmp()` or `longjmp()` is called from `main()`, then `terminate()` is not called for an unhandled exception.

Handling C++ Exceptions

6.7 C++ Exceptions, lib\$establish and vaxc\$establish

6.7 C++ Exceptions, lib\$establish and vaxc\$establish

If a C++ function calls either the `lib$establish()` or the `vaxc$establish()` routine, then C++ exceptions support is disabled for that function. This means the following:

- No exceptions can be caught by the function's catch handlers.
- No destructors are called for the function's automatic data if an exception propagates through the function.
- The `unexpected()` function is not called for that function.
- If either `lib$establish()` or `vaxc$establish()` is called from `main()`, then `terminate()` is not called for an unhandled exception.

6.8 Performance Considerations

The compiler optimizes the implementation of exception handling for normal execution, as follows:

- Applications that do not use C++ exceptions and are compiled with the `/NOEXCEPTIONS` qualifier incur no run-time or image size overhead.
- Applications compiled with exceptions enabled that have try blocks or automatic objects with destructors incur an increase in image size.
- As much as possible, the run-time overhead for exceptions is incurred when throwing and catching exceptions, not when entering and exiting try blocks normally.

6.9 C++ Exceptions and Threads

C++ exceptions are thread safe. This means that multiple threads within a process can throw and catch exceptions concurrently. However, exceptions do not propagate from one thread to another, nor can one thread catch an exception thrown by another thread.

The `set_terminate()` and `set_unexpected()` functions set the `terminate()` and `unexpected()` handlers for the calling thread. Therefore, each thread in a program has its own `terminate()` and `unexpected()` handlers.

If you want every thread in your program to use the same nondefault `terminate()` or `unexpected()` handlers, then you must call the `set_terminate()` and `set_unexpected()` functions separately from each thread.

Handling C++ Exceptions

6.9 C++ Exceptions and Threads

By default, the C++ exception package allows the delivery of the `CMA$_EXIT_THREAD` condition, but not the `CMA$_ALERTED` condition. This latter condition is raised to a thread that is being cancelled. The following routine (`test_thread`) allows an application to control the default behavior of these two conditions:

```
int cxxl$catchable_condition (int condition, int on_or_off);
```

The condition is either `CMA$_EXIT_THREAD` or `CMA$_ALERTED`. A value of zero means the program does not want the condition to result in a catch clause receiving the exception. This is the default behavior for `CMA$_ALERTED`. A value of nonzero means the program does want the condition to result in the catch clause of the thread to receive control when the exception is raised. The behavior is undefined for any other condition value passed.

The return value of the routine is the previous setting for the passed condition value:

```
#include <pthread.h>
#include <cxx_exception.h>
#include <cma$def.h>
...
static void *test_thread (...) {
...
try {
...
} catch (chf$signal_array *p) {
    switch (p->chf$l_sig_name)
    {
        case CMA$_ALERTED:
            printf (" test_thread caught CMA$_ALERTED\n");
            break;
        default:
            printf (" test_thread caught (%d)\n", p->chf$l_sig_name);
            break;
    }
}
}

int main () {
...
if (cxxl$catchable_condition(CMA$_ALERTED,1))
    printf (" CMA$_ALERTED continues to be catchable\n");
else printf (" CMA$_ALERTED is now catchable\n");
}
```

Handling C++ Exceptions

6.9 C++ Exceptions and Threads

```
...  
    pthread_create (&thread, ...);  
...  
    pthread_cancel (thread);  
...  
}
```

For more information about threads, see the *Guide to DECthreads* manual.

6.10 Debugging with C++ Exceptions *(Alpha only)*

You can use the OpenVMS Debugger `set break/exception` command to set a breakpoint when an exception is thrown. You can use the `show calls` command to determine the location where the exception was thrown.

The C++ Standard Library

The C++ Standard Library provided with this release defines a complete specification of the C++ International Standard, with some differences, as described in the online release notes in:

```
SYS$HELP:CXX_RELEASE_NOTES.PS
```

Note that portions of the C++ Standard Library have been implemented in HP C++ using source licensed from and copyrighted by Rogue Wave Software, Inc. Information pertaining to the C++ Standard Library has been edited and incorporated into HP C++ documentation with permission of Rogue Wave Software, Inc. All rights reserved.

Some of the components in the C++ Standard Library are designed to replace nonstandard components that are currently distributed in the Class Library. HP will continue to provide the Class Library in its nonstandard form. However, you now have the option of using new standard components.

This chapter provides more information on the HP C++ implementation of the Standard Library, including upward compatibility, compiling, linking, and thread safety. Small example programs showing how to use the C++ standard library are located in the directory `SYS$COMMON:[SYSHLP.EXAMPLES.CXX]`.

The following are Standard Library qualifiers introduced with HP C++ Version 6.0:

/[NO]USING_STD

Controls whether standard library header files are processed as though the compiled code were written as follows:

```
using namespace std;
#include <header>
```

These qualifiers are provided for compatibility for users who do not want to qualify use of each standard library name with `std::` or put `using namespace std;` at the top of their sources.

The C++ Standard Library

`/USING_STD` turns implicit using namespace `std` on; this is the default when compiling `/STANDARD=ARM`, `/STANDARD=MS`, or `/STANDARD=RELAXED`.

`/NOUSING_STD` turns implicit using namespace `std` off; this is the default when compiling `/STANDARD=STRICT_ANSI`.

`/ASSUME=[NO]STDNEW`

Controls whether calls are generated to the ANSI or pre-ANSI implementation of the operator `new()`. On memory allocation failure, the ANSI implementation throws `std::bad_alloc`, while the pre-ANSI implementation returns 0.

`/ASSUME=STDNEW` generates calls to the ANSI `new()` implementation; this is the default when compiling with `/STANDARD=RELAXED` and `/STANDARD=STRICT_ANSI`.

`/ASSUME=NOSTDNEW` generates calls to the pre-ANSI `new()` implementation; this is the default when compiling with `/STANDARD=ARM` and `/STANDARD=MS`.

`/ASSUME=[NO]GLOBAL_ARRAY_NEW`

Controls whether calls to global array `new` and `delete` are generated as specified by ANSI. Pre-ANSI global array `new` generated calls to operator `new()`. According to ANSI, use of global array `new` generate calls to operator `new() []`.

`/ASSUME=GLOBAL_ARRAY_NEW` generates calls to operator `new() []` for global array `new` expressions such as `new int[4]`; this is the default when compiling `/STANDARD=RELAXED`, `/STANDARD=STRICT_ANSI`, and `/STANDARD=MS`.

`/ASSUME=NOGLOBAL_ARRAY_NEW` generates calls to operator `new()` for global array `new` expressions such as `new int[4]` and preserves compatibility with Version 5.n; this is the default when compiling `/STANDARD=ARM`. .)

7.1 Important Compatibility Information

On Alpha systems, because the standardization process for the C++ Standard Library is not yet completed, HP cannot guarantee that this version of the library is compatible with any past or future releases. We ship the run-time portion of the library in object form, not in shareable form, to emphasize this situation. *(Alpha only)*

On I64 systems, the standard library is distributed as a system shareable image `SYS$LIBRARY:CXXL$RWRTL.EXE`, and also in object form in the system object library `STARLET.OLB`. *(I64 only)*

The C++ Standard Library

7.1 Important Compatibility Information

The following sections describe specific compatibility issues.

7.1.1 `/[NO]USING_STD` Compiler Compatibility Qualifier

All standard library names in HP C++ are inside the namespace `std`. Typically you would qualify each standard library name with `std::` or put `using namespace std;` at the top of your source file.

To make things easier for existing users, `using namespace std;` is included in a file provided with every standard library header when you are in ARM, MS, or RELAXED compiler modes. This is not the default in STRICT_ANSI mode.

The compiler supplied qualifiers `/NOUSING_STD` and `/USING_STD` can be used to override the default. `/NOUSING_STD` turns the implicit `using namespace std;` off; `/USING_STD` turns it on.

7.1.2 Pre-ANSI/ANSI Iostreams Compatibility

The C++ Standard Library offers support for the standard iostream library based on the C++ International Standard. As defined by the standard, iostream classes are in the new header files `<iostream>`, `<ostream>`, `<istream>`, and so on (no `.h` or `.hxx` extension).

For backward compatibility, the pre-ANSI iostream library is still provided. The two libraries exhibit subtle differences and incompatibilities.

Users can choose which version (ANSI or pre-ANSI) of iostreams they want to use; either version of iostreams can be integrated seamlessly with the new Standard Library and string functionality.

To accomplish this goal, macros called `__USE_STD_Iostream` and `__NO_USE_STD_Iostream` are provided. If you do not set these macros explicitly, the default in ARM, MS, and RELAXED modes is to use the pre-ANSI iostream library. In STRICT_ANSI mode, the default is to use the ANSI iostream library.

Note that for the most part, support for pre-ANSI iostreams is contained in headers with `.h` or `.hxx` extensions. This is not the case for `iostream.h/iostream.hxx`, `fstream.h/fstream.hxx`, `strstream.h/strstream.hxx`, and `iomanip.h/iomanip.hxx`. In these cases, the iostream library provided is controlled solely by the `/STANDARD` compilation choice and use of `__USE_STD_Iostream/__NO_USE_STD_Iostream`.

You override the default by defining `__USE_STD_Iostream` or `__NO_USE_STD_Iostream` on either the command line or in your source code.

The C++ Standard Library

7.1 Important Compatibility Information

In ARM, MS, and RELAXED modes, specify use of the ANSI iostreams in one of the following ways:

- Enter `/DEFINE=(__USE_STD_Iostream)` on the command line.
- Put the following in your source file before any include files:

```
#ifndef __USE_STD_Iostream
#define __USE_STD_Iostream
#endif
```

In STRICT_ANSI mode, specify use of the pre-ANSI iostreams in one of the following ways:

- Enter `/DEFINE=(__NO__USE_STD_Iostream)` on the command line.
- Put the following in your source file before any include files:

```
#ifndef __NO_USE_STD_Iostream
#define __NO_USE_STD_Iostream
#endif
```

You receive a `#error` warning if

- you compile in a mode indicating you want ANSI behavior; that is, `/STANDARD=STRICT_ANSI`,
- you enter a header with a `.h` or `.hxx` (for example, `#include <iostream.h>`).

You can avoid the error by compiling with `/DEFINE=(__NO_USE_STD_Iostream)`.

Many of the other headers, `<string>` for example, make use of the `iostream` classes. The default version of iostreams that is automatically included when you include one of these headers depends on the mode you compile in and the setting of the macros `__USE_STD_Iostream` and `__NO_USE_STD_Iostream` as described earlier.

Because the standard locale class and the standard `iostream` class are so closely tied, you cannot use the standard locale class with the pre-ANSI `iostream` classes. If you want to use locale, you must use the ANSI `iostream` classes.

It is possible to use the pre-ANSI and the ANSI `iostream` library in the same source file, because all the standard `iostream` names (that is, `cout`, `cin`, and so on) are in namespace `std`, and all the pre-ANSI names are in the global namespace. This is not recommended, though, because there is no guarantee of stream objects being the same size or, for example, of `::cout` being in sync with `std::cout`.

The C++ Standard Library

7.1 Important Compatibility Information

Nevertheless, if you want to combine them, you must recognize that the underlying ANSI iostream is called `iostream_stdimpl.hxx` and that the pre-ANSI header is called `iostream_impl.hxx`. The following example shows how to include a pre-ANSI header before and ANSI header:

```
#include <stdlib.h>
#undef __USE_STD_IOSTREAM
#include <iostream_impl.hxx>
#define __USE_STD_IOSTREAM
#include <iostream_stdimpl.hxx>

int main()
{
    std::string s("abc");
    ::cout << "abc" << endl;          // pre-standard iostreams
    std::cout << "abc" << std::endl; // standard iostreams
    return EXIT_SUCCESS;
}
```

If you include an ANSI iostreams header before a pre-ANSI iostreams header, follow these steps:

1. Compile your source using `/NOUSING_STD`.
2. Use the `__USE_STD_IOSTREAM` macro as shown in the following example. You must define `__USE_STD_IOSTREAM` at the end of your include file list so that the template definition files (the `.cc` files) are included in the correct mode.

```
// Compile this with /nousing_std
#include <stdlib.h>
#define __USE_STD_IOSTREAM
#include <iostream_stdimpl.hxx>
#undef __USE_STD_IOSTREAM
#include <iostream_impl.hxx>
#define __USE_STD_IOSTREAM // so the template definition files are ok

int main()
{
    std::string s("abc");
    ::cout << "abc" << endl; // pre-standard iostreams
    std::cout << "abc" << std::endl; // standard iostreams
    return EXIT_SUCCESS;
}
```

The C++ Standard Library

7.1 Important Compatibility Information

7.1.3 Support for pre-ANSI and ANSI operator new()

The Standard C++ Library supports the ANSI implementation of the operator `new()` as well as the pre-ANSI implementation of operator `new()`. The ANSI implementation throws `std::bad_alloc` on memory allocation failures.

The pre-ANSI implementation of the operator `new()` returns 0 on memory allocation failures. Because the ANSI behavior is incompatible with pre-ANSI applications, a compile time qualifier has been added (`/ASSUME=[NO]STDNEW`) to control whether calls to ANSI `new()` or pre-ANSI `new` are generated.

The following examples show how ANSI versus pre-ANSI `new()` check for memory allocation. First, here is an ANSI `new()` check for memory allocation failure:

```
try {
    myobjptr = new (myobjptr);
}
catch (std::bad_alloc e) {
    cout << e.what() << endl;
};
```

The following example shows a pre-ANSI `new()` check for memory allocation failure:

```
if ((myobjptr = new (myobjptr)) == 0)
    call_failure_routine();
```

When upgrading pre-ANSI `new()` code to work with the C++ Standard Library you also can use the `nothrow` version of ANSI `new()`. To do so in the pre-ANSI example, you could recode it as follows:

```
if ((myobjptr = new (myobjptr, nothrow)) == 0)
    call_failure_routine();
```

Two command line qualifiers are available in the compiler to control whether calls are generated to the ANSI or pre-ANSI implementation of operator `new()`:

- Use the `/ASSUME=STDNEW` qualifier to generate calls to the ANSI `new()` implementation.
- Use the `/ASSUME=NOSTDNEW` qualifier to generate calls to the pre-ANSI `new()` implementation. You can override global `new()` by declaring your own functions.

When compiling with `/STANDARD=RELAXED` or `/STANDARD=STRICT_ANSI`, `/ASSUME=STDNEW` is the default.

The C++ Standard Library

7.1 Important Compatibility Information

When compiling with `/STANDARD=ARM` and `/STANDARD=MS`, `/ASSUME=NOSTDNEW` is the default. The compiler defines the macro `__STDNEW` when the `/ASSUME=STDNEW` qualifier is specified.

7.1.4 Overriding operator `new()` *(Alpha only)*

On Alpha systems, the ability to override the library version of global operator `new()` and global operator `delete()` is available with OpenVMS Version 6.2 and later. If you want to define your own version of global operator `new()` on OpenVMS systems, you must define your own version of global operator `delete()` and vice versa. To define a global operator `new()` or a global operator `delete()` to replace the version used by the C++ Standard Library or the C++ Class Library, or both, follow these steps:

1. Define a module to contain two entry points for your version of global operator `new()`. You must code the module so that it is always compiled either with the `/ASSUME=STDNEW` or with the `/ASSUME=NOSTDNEW` qualifier.
2. If you code your module to compile with `/ASSUME=STDNEW`, follow instructions in the next subsection. If you code your module to compile with `/ASSUME=NOSTDNEW`, follow instructions in the subsection **Compiling with `/ASSUME=NOSTDNEW`**.

Compiling with `/ASSUME=STDNEW`

1. Verify that your module contains two entry points for your version of global operator `new()`. One entry point, which has the name `__nw__XUi` (`/MODEL=ARM`) or `__7__nw__FUi` (`/MODEL=ANSI`), is used to override global operator `new()` in the Class Library. The other entry point, which has the name `new`, is used to override global operator `new()` in the Standard Library.
2. Define global operator `new()` in terms of the entry point `new`. Code `__nw__XUi` (for `/MODEL=ARM`) or `__7__nw__FUi` (for `/MODEL=ANSI`) to call operator `new`. Your module appears as follows:

```
#include <new>
...
using namespace std;
```

The C++ Standard Library

7.1 Important Compatibility Information

```
// Redefine global operator new(),
// entry point into C++ Standard Library based on
// compiling /assume=stdnew. This also overrides user
// calls to operator new().
void *operator new(size_t size) throw(std::bad_alloc) {
    printf("in my global new\n");
    ...
    void *p = malloc(size);
    return(p);
}

// redefine global operator delete()
void operator delete(void *ptr) throw() {
    free (ptr);
}

// entry point into C++ Class Library
#ifdef _MODEL_ANSI
extern "C" void *_7__stdnw__FUi(size_t size) {
#else // _MODEL_ARM
extern "C" void *_nw__XUi(size_t size) {
#endif
    printf("in my new\n");
    return ::operator new(size);
}
```

Compiling with /ASSUME=NOSTDNEW

1. Verify that your module contains two entry points for your version of global operator new(). One entry point, which has the name cxx1\$__stdnw__XUi (for /MODEL=ARM) or cxx1\$__7__stdnw__FUi (for /MODEL=ANSI), is used to override global operator new() in the Standard Library. The other entry point, which has the name new, is used to override global operator new() in the Class Library.
2. Define global operator new() in terms of the entry point new. Code cxx1\$__stdnw__XUi (/MODEL=ARM) or cxx1\$__stdnw__FUi (/MODEL=ANSI) to call operator new. Your module appears as follows:

```
#include <new>
...
using namespace std;

// Redefine global <code_example>(operator new()),
// entry point into C++ Class Library based on
// compiling /assume=nostdnew
void *operator new(size_t size) {
    printf("in my global new\n");
    ...
    void *p = malloc(size);
    return(p);
}
```

The C++ Standard Library

7.1 Important Compatibility Information

```
// redefine global operator delete()
void operator delete(void *ptr) {
    free (ptr);
}

// entry point into C++ Standard Library
#ifdef __MODEL_ANSI
extern "C" void *cxxl$__7__stdnw__FU(size_t size) {
#else // __MODEL_ARM
extern "C" void *cxxl$__stdnw__XU(size_t size) {
    return ::operator new(size);
}
}
```

3. Link your program using the /NOSYSSHR qualifier of the LINK command. You must also link with a linker options file that includes the shareable images your program requires. (This is because some components of OpenVMS systems ship only in shareable form.) The file contains at least the shareable images shown below. The options file cannot contain, DECC\$SHR, because it contains the definitions of new() and delete() that you are attempting to override. So your LINK command will be similar to the following:

```
$ CXXLINK TEST,SYS$LIBRARY:STARLET.OLB/INCLUDE=CXXL_INIT, -
SYS$DISK:[]AVMS_NOSYSSHR.OPT/OPT/NOSYSSHR
```

where AVMS_NOSYSSHR.OPT is:

```
SYS$SHARE:CMA$TIS_SHR/SHARE
SYS$SHARE:LIBRTL/SHARE
```

Linking /NOSYSSHR is the only way to override calls to new() and delete() in the C++ Class Library and C++ Standard Library.

If the set_new_handler() function is referenced when overriding operator new() and delete(), “multiply defined” linker warnings will result. To remove these warnings, the set_new_handler() function must also be overridden. Using set_new_handler() when the operator new() and delete() functions are being overridden, requires that the set_new_handler() function be defined in terms of the user provided operator new() and delete() functions.

7.1.5 Overriding operator new() *(I64 only)*

Overriding operators new and delete has been simplified on I64 systems. If user code overrides any of the new and delete operators, the compiler and library picks up the overridden versions without any other changes to the source code or the command line. Changes such as those described for Alpha systems in Section 7.1.4 are unnecessary and will not work on I64 systems.

The C++ Standard Library

7.1 Important Compatibility Information

7.1.6 Support for Global array new and delete Operators

HP C++ Version 6.*n* and higher fully supports the array new and delete operators as described in the ANSI standard. Previous versions did not.

You might therefore encounter a compatibility problem if you have overridden the run-time library's operator new() with your own version.

For example:

```
#include <stdlib.h>
#include <iostream.h>

inline void* operator new(size_t s) {
    cout << "called my operator new" << endl;
    return 0;
}

int main() {
    new int; // ok, this still calls your own
    new int[4]; // In V6.0 calls the C++ library's operator new[]
    return EXIT_SUCCESS;
}
```

In older versions, both new int and new int[4] would generate a call to operator new() (they would just be asking for different sizes). With the current compiler, new int still generates a call to operator new(). However, new int[4] generates a call to operator new()[]. This means that if you still want to override the library's operator new you must do one of the following:

1. Provide your own definition of operator new()[].
2. Use the /ASSUME=NOGLOBAL_ARRAY_NEW qualifier.

The /ASSUME=NOGLOBAL_ARRAY_NEW qualifier converts all expressions such as new int[4] to calls to the global operator new(), thus preserving compatibility with older compiler versions.

Note that this qualifier has *no* effect on class-specific array operator new and delete; it affects only the global operators.

When compiling with /STANDARD=RELAXED or /STANDARD=STRICT_ANSI, and /STANDARD=MS modes, /ASSUME=GLOBAL_ARRAY_NEW is the default.

When compiling with /STANDARD=ARM, /ASSUME=NOGLOBAL_ARRAY_NEW is the default. A macro __GLOBAL_ARRAY_NEW is predefined by the compiler when /ASSUME=GLOBAL_ARRAY_NEW is used.

The C++ Standard Library

7.1 Important Compatibility Information

7.1.7 IOStreams Expects Default Floating-Point Format

The C++ standard library IOStreams expects floating-point values in the default floating-point format for each platform: G_FLOAT on Alpha systems and IEEE on I64 systems. Using standard library IOStreams for processing floating-point values in a different format (for example, in a program compiled /FLOAT=IEEE on Alpha or /FLOAT=G_FLOAT on I64) is not supported. The C++ class library does not have this restriction.

7.2 How to Build Programs Using the C++ Standard Library

Building programs that use the C++ Standard Library requires the following changes in usage of the C++ compiler and linker commands:

- The CXX command line no longer needs to include the /ASSUME=NOHEADER_TYPE_DEFAULT qualifier because this is now the default. Similarly, the command line no longer needs to include the /TEMPLATE=AUTO qualifier because the compiler performs automatic template instantiation by default.
- On Alpha systems, to link a program that uses the C++ Standard Library, you must use the CXXLINK command in place of the LINK command. The CXXLINK command continues the automatic template instantiation process, includes the Standard Library run-time support (SYS\$LIBRARY:LIBCXXSTD.OLB) at link time, and creates the final image. See Section 1.3 for more details. *(Alpha only)*

On I64 systems, to link a program that uses the C++ Standard Library, you must use either the CXXLINK facility or OpenVMS Linker. See Section 1.4 for more details. *(I64 only)*

For example, to build a program called prog.cxx that uses the Standard Library, you can use the following commands:

```
$ CXX prog.cxx
$ CXXLINK prog.obj
```

Thread Safety

The Standard Library provided with this release is thread safe but not thread reentrant. Thread safe means that all library internal and global data is protected from simultaneous access by multiple threads. In this way, internal buffers as well as global data like cin and cout are protected during each individual library operation. Users, however, are responsible for protecting their own objects.

The C++ Standard Library

7.2 How to Build Programs Using the C++ Standard Library

According to the C++ standard, results of recursive initialization are undefined. To guarantee thread safety, the compiler inserts code to implement a spinlock if another thread is initializing local static data. If recursive initialization occurs, the code deadlocks even if threads are not used.

7.3 Optional Switch to Control Buffering *(Alpha only)*

The `inplace_merge`, `stable_sort`, and `stable_partition` algorithms require the use of a temporary buffer. Two methods are available for allocating this buffer:

- Preallocate 16K bytes of space on the stack.
- Allocate the required amount of storage dynamically.

By default, the current HP C++ Standard Library makes use of the preallocated buffer, which avoids the overhead of run-time allocation. If your application requires a buffer that exceeds 16K, it cannot take advantage of this default.

If you are concerned with minimizing the use of stack space in your program, or if your application requires a buffer that exceeds 16K, define the `__DEC_DYN_ALLOC` macro to enable dynamic buffering. Do this by adding the following to your compile command line:

```
/DEFINE=__DEC_DYN_ALLOC
```

7.4 Enhanced Compile-time Performance of ANSI Iostreams

To speed the compile-time performance of programs that use the standard `iostream` and `locale` components, the Standard Library includes many common template instantiations of these components

To force programs to create instantiations at compile-time (for example, if you want to debug them and thus need them to be compiled with the `/DEBUG` qualifier), define the macro `__FORCE_INSTANTIATIONS` *(Alpha only)* on the command line by specifying `/DEFINE=(__FORCE_INSTANTIATIONS)`. This definition suppresses the `#pragma do_not_instantiate` directives in the headers so that the compiler creates the instantiations in your repository directory.

You must then specify the `/REPOSITORY=` qualifier to force the compiler to link your instantiations instead of those in the Standard Library.

7.5 Using RMS Attributes with iostreams

The standard library class `fstream` constructors and `open()` member function do not support different RMS attributes, for example, creating a stream-lf file.

To work around this restriction, use the C library `creat()` or `open()` call, which returns a file descriptor, and then use the `fstream` constructor, which accepts a file descriptor as its argument. For example:

```
#define __USE_STD_IOSTREAM
#include <fstream>

int main()
{
    int fp;

    // use either creat or open
    //if ( !(fp= creat("output_file.test", 0, "rfm=stmlf")) )

    if ( !(fp= open("output_file.test", O_WRONLY | O_CREAT | O_TRUNC , 0,
"rfm=stmlf")) )
        perror("open");

    ofstream output_file(fp); // use special constructor, which takes
                             // a file descriptor as argument
    // ...
}
```

Note that this coding is not allowed if you compile with `/STANDARD=STRICT_ANSI`, because the constructor in the example is an extension to the C++ standard interface.

7.6 Upgrading from the Class Library to the Standard Library

The following discussion guides you through upgrading the Class Library code to use the Standard Library, specifically replacing the vector and stack classes in the `vector.hxx` header file to the Standard Library vector and stack classes.

7.6.1 Upgrading from the Class Library Vector to the Standard Library Vector

To change your code from using the Class Library vector to the Standard Library vector, consider the following actions:

- Change the name of your `#include` statement from `<vector.h>` or `<vector.hxx>` to `<vector>`.
- Remove the `vectordeclare` and `vectorimplement` declarations from your code.

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

- Change all `vector(type)` declarations to `vector<type>`. For example, `vector(int) vi` should become `vector<int> vi`.
- The following member functions are replaced in the Standard Library:

Nonstandard Vector Function	Standard Library Vector Function
<code>elem(int index)</code>	<code>operator[] (size_t index)</code> (no bounds checking)
<code>operator[] (int index)</code>	<code>at(size_t index)</code> (bounds checking)
<code>setsize(int newsize)</code>	<code>resize(size_t newsize)</code>

- When copying vectors of unequal lengths, note that the Standard Library vector has a different behavior as follows:
When using the Standard Library vector, if the target vector is smaller than the source vector, the target vector automatically increases to accommodate the additional elements.
The Class Library vector displays an error and aborts when this situation occurs.
- Note that another difference in behavior occurs when you specify a negative index for a vector.
The Class Library vector class detects the negative specification and issues an error message. However, the Standard Library vector silently converts the negative value to a large positive value, because indices are represented as type `size_t` (unsigned int) rather than `int`.
- When an out-of-bounds error occurs, the Class Library vector prints an error message and aborts, whereas the Standard Library vector throws an out-of-range object.

7.6.2 Upgrading from the Class Library Stack to the Standard Library Stack

To change your code from using the existing stack to the Standard Library stack, consider the following actions:

- Change the name of your `#include` statement from `<stack.h>` or `<stack.hxx>` to `<stack>`.
- Remove the `stackdeclare` and `stackimplement` declarations from your code.
- Change all `stack(type)` declarations to `stack<type, deque<type> >`. For example, `stack(int) si` should become `stack<int, deque<int> > si`.

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

- Do not specify an initial size for a Standard Library stack. The stack must start out empty and grow dynamically (as you push and pop).
- The following member functions are not supported or have different semantics:

Class Library Stack	Standard Library Stack
<code>size_used()</code>	Does not exist because the <code>size()</code> function always is equal to the <code>size_used()</code> function.
<code>full()</code>	Does not exist because the stack always is full.
<code>pop()</code>	Does not return the popped element. To simulate Class Library behavior, first obtain the element as the return type from the <code>top()</code> function and then call the <code>pop()</code> function. For example, change <code>int i=s.pop();</code> to the following: <pre>int i=s.top(); s.pop();</pre>

- The Standard Library stack differs from the Class Library stack in the way errors are detected. Unlike the nonstandard stack, you cannot overflow a Standard Library stack because space is allocated dynamically as you push elements onto the stack.

7.6.3 Upgrading from the Class Library String Package Code

The Standard Library `basic_string` can replace the Class Library String Package.

The following list guides you through upgrading nonstandard code to use the Standard Library `basic_string`:

- Change `#include <string.h>` or `#include <string.hxx>` to `#include <string>`.
- Change all declarations of `String` to `string` (uppercase `S` to lowercase `s`).
- On Alpha systems, when compiling with the `__DEC_STRING_COMPATIBILITY` macro defined, the String Package allowed assignment of a `string` directly to a `char*`; however, the `basic_string` library does not allow this. You can assign the `string`'s `const char*` representation using the `c_str()` or `data()` `basic_string` member functions. For example:

```
string s("abc");
char* cp = s; // not allowed
const char* cp = s.data(); // ok
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

The state of the string is undefined if the result of `data()` is cast to a non-const `char*` and then the value of that `char*` is changed.

- The String Package member functions `upper()` and `lower()` are not in the `basic_string` library. You can write these functions as nonmember functions, as follows:

```
template <class charT, class traits, class Allocator>
inline
basic_string<charT, traits, Allocator>
upper(const basic_string<charT, traits, Allocator>& str) {
    basic_string<charT, traits, Allocator> newstr(str);
    for (size_t index = 0; index < str.length(); index++)
        if (islower(str[index]))
            newstr[index] = toupper(str[index]);
    return newstr;
}

template <class charT, class traits, class Allocator>
inline
basic_string<charT, traits, Allocator>
lower(const basic_string<charT, traits, Allocator>& str) {
    basic_string<charT, traits, Allocator> newstr(str);
    for (size_t index = 0; index < str.length(); index++)
        if (isupper(str[index]))
            newstr[index] = tolower(str[index]);
    return newstr;
}
```

Then instead of calling `upper()` and `lower()` as member functions of the `basic_string`, pass the string as an argument. For example:

```
s2 = s1.upper(); // does not compile
s2 = upper(s1); // ok
```

- The String Package `match()` member function does not exist. Equivalent functionality exists in the Standard Library algorithm `mismatch()`, although using it is more complicated. For example:

```
string s1("abcdef");
string s2("abcdgf");
assert(s1.match(s2)==4); // does not compile
pair<string::iterator, string::iterator> p(0,0); // ok
p=mismatch(s1.begin(), s1.end(), s2.begin());
assert(p.first-s1.begin()==4);
string s3 = s1;
p=mismatch(s1.begin(), s1.end(), s3.begin());
assert(p.first == s1.end()); // everything matched
```

- The String Package `index()` member function does not exist. The `basic_string` library equivalent is `find()`.

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

- The String Package constructor that takes two positional parameters (a start and end position) and constructs a new string does not exist. It is replaced in the `basic_string` library with the member function `substr()`. For example:

```
string s1("abcde");  
string s2 = s1(1,3); // does not compile  
string s2 = s1.substr(1,3); // ok
```

- Many previously undetected run-time errors now throw standard exceptions in the String library.

7.6.4 Upgrading from the Class Library Complex to the ANSI Complex Class

Note

On I64 systems, the Class Library Complex package has been removed, so upgrading to the Standard Library complex class is the only option on this platform. *(I64 only)*

This section explains how to upgrade from the pre-ANSI complex library to the current standard complex library.

In the pre-ANSI library, complex objects are not templated. In the ANSI library, complex objects are templated on the type of the real and imaginary parts. The pre-ANSI library assumes the type is double, whereas the ANSI library provides specializations for float, double, and long double as well as allowing users to specialize on their own floating point types.

Mathematical error checking is not supported in the ANSI library. Users who rely on detection of underflow, overflow, and divide by zero should continue using the pre-ANSI complex library.

The following is a detailed list of important changes:

- Change `#include <complex.h>` or `#include <complex.hxx>` to `#include <complex>`.
- Change all declarations of `complex` to `complex<double>`, for example:

```
complex c;
```

Change to:

```
complex<double> c;
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

- The `polar()` function no longer supplies a default value of 0 for the second argument. Users will have to explicitly add it to any calls that have only one argument, for example:

```
complex c;  
c = polar(c); // get polar
```

Change to:

```
complex<double> c;  
c = polar(c,0.0);
```

- If you are calling a mathematical function or mathematical operator that takes scalars as arguments (`polar()` for example), then you must adjust the arguments you pass in to be the same type as the complex template parameter type. For example, you would have to change:

```
complex c = polar(0,0);  
complex c2 = c+1;
```

Change to:

```
complex<double> c = polar(0.0,0.0); // 0.0 is double  
complex<double> c2= c + 1.0; // 1.0 is double
```

- The `complex_zero` variable is not declared in the complex header file. If you want to use it, you will have to declare it yourself. For example, add the following to the top of your source file:

```
static const complex<double> complex_zero(0.0,0.0);
```

- The `sqr()` and `arg1()` functions are gone. If you want to continue to use them, you should define them in one of your own headers, using the following definitions:

```
template <class T>  
inline complex<T> sqr(const complex<T>& a)  
{  
    T r_val(real(a));  
    T i_val(imag(a));  
    return complex<T>  
        (r_val * r_val -  
         i_val * i_val,  
         2 * r_val * i_val);  
}  
template <class T>  
inline T arg1(const complex<T>& a)  
{  
    T val = arg(a);  
    if(val > -M_PI && val <= M_PI)  
        return val;  
}
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

```
    if(val > M_PI)
        return val - (2*M_PI);
    // val <= -PI
    return val + (2*M_PI);
}
```

- The `pow(complex, int)` function is no longer provided. You must use `pow(complex<double>, double)`. This means changing calls such as:

```
pow(c,1);
```

Change to:

```
pow(c,1.0);
```

This might yield different results. If the function previously was underflowing or overflowing, it might not continue to happen.

- The complex output operator (`<<`) does not insert a space between the comma and the imaginary part. If you want the space, you would need to print the real and imaginary parts separately, adding your own comma and space; that is:

```
complex<double> c;
cout << "(" << c.real() << ", " << c.imag() << ")"; // add extra space
```

- The complex input operator (`>>`) does not raise an `Objection` if bad input is detected; it instead sets input stream's state to `ios::failbit`.
- Floating point overflow, underflow, and divide by zero do not set `errno` and will cause undefined behavior. Complex error checking and error notification is planned for a subsequent release.
- You should no longer need to link your program explicitly with the complex library. It is automatically linked in as part of the Standard Library. However, you must still explicitly link in the C math library, as shown in the following example:

```
#include <stdlib.h>
#include <complex>

int main() {
    complex<double> c1(1,1), c2(3.14,3.14);
    cout << "c2/c1: " << c2/c1 << endl;
    return EXIT_SUCCESS;
    % cxx example.cxx #error
    % cxx example.cxx -lm #okay
}
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

7.6.5 Upgrading from the Pre-ANSI iostream library to the HP C++ Standard Library

This section explains how to upgrade from the pre-ANSI iostream library to the ANSI iostream library. In this section, pre-ANSI iostreams refers to versions of the iostream library found in the Class Library; ANSI iostreams refers to versions found in the HP C++ Standard Library.

There are a number of differences between the pre-ANSI and ANSI iostream library. One major difference between the pre-ANSI and ANSI iostream library is that the ANSI library is templated on the object input/output on which operations are being performed. In the pre-ANSI library, iostreams has no templates. The ANSI library also provides specializations for `char` and `wchar_t`.

Important differences are as follows:

- With the current compiler, you access the pre-ANSI iostream library by default in non `strict_ansi` compiler modes. You can control the version of iostreams you use with the `__USE_STD_Iostream` and `__NO_USE_STD_Iostream` macros. If you want to use the ANSI iostream library, do either of the following:

Enter `/DEFINE=(__USE_STD_Iostream)` on the command line.
Put the following in your source file before any include files:

```
#ifndef __USE_STD_Iostream)
#define __USE_STD_Iostream)
#endif
```

- Header names are different in the ANSI library, so to use ANSI iostreams, change the iostreams headers you include as follows:

From	To
<code>#include <iostream.h></code> <code>#include <iostream.hxx></code>	<code>#include <iostream></code>
<code>#include <fstream.h></code> <code>#include <fstream.hxx></code>	<code>#include <fstream></code>
<code>#include <strstream.h></code> <code>#include <strstream.hxx></code>	<code>#include <strstream></code>
<code>#include <iomanip.h></code> <code>#include <iomanip.hxx></code>	<code>#include <iomanip></code>

- All Standard Library names in the ANSI iostream library are in namespace `std`. Typically you would qualify each Standard Library name with `std::` or put using namespace `std`; at the top of your source file.

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

To facilitate upgrading in all but `STRICT_ANSI` mode, using namespace `std`; is set by default. In `STRICT_ANSI` mode, after including an ANSI iostream header, you must qualify each name inside namespace `std` individually or do

```
using namespace std;
```

- In the pre-ANSI iostream library, including `<iomanip.h>` or `<strstream.h>` gave you access to `cout`, `cin`, and `cerr`. To access the predefined streams with the ANSI iostream library, make the following changes:

change	change
<code>#include <iomanip.h></code>	<code>#include <strstream.h></code>
to	to
<code>#include <iomanip></code>	<code>#include <strstream></code>
<code>#include <iostream></code>	<code>#include <iostream></code>
<code>#include using namespace std;</code>	<code>using namespace std;</code>

- The `istream::ipfx`, `istream::isfx`, `ostream::opfx`, `ostream::osfx` do not exist in the ANSI iostreams. Their functionality is provided by the sentry class found in `basic_istream` and `basic_ostream`, respectively.

Common prefix code is provided by the sentry's constructor. Common suffix code is provided by the sentry's destructor. As a result, calls to `ipfx()`, `isfx()`, `opfx()`, and `osfx()` have their functionality replaced by construction and destruction of `std::istream::sentry` objects and `std::ostream::sentry` object respectively. For example:

```
#include <iostream.hxx>
void func (istream &is)
{
    if (is.ipfx())
        ...
    is.isfx();
}
```

Would be coded as:

```
#include <iostream>
void func (istream &is)
{
    istream::sentry ipfx(is);
    if (ipfx)
        ...
    //is.isfx(); implicit in dtor
}
```

```
#include <iostream.hxx>
void func (ostream &os)
{
    if (os.opfx())
        ...
    os.osfx();
}
```

Would be coded as:

```
#include <literal><iostream>
void func (ostream &os)
{
    ostream::sentry opfx(os);
    if (opfx)
        ...
    //os.osfx(); implicit in dtor
}
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

- The following macros from the pre-ANSI `<iomanip.h>` are no longer available in `<iomanip>`:

```
SMANIP, IMANIP, OMANIP, IOMANIP,  
SAPP, IAPP, OAPP, IOAPP,  
SMANIPREF, IMANIPREF, OMANIPREF, IOMANIPREF,  
SAPPREF, IAPPREF, OAPPREF, IOAPPREF
```

You can add them yourself, but their use will not be portable.

- The `streambuf::stossc()` function, which advances the get pointer forward by one character in a stream buffer, is not available in the ANSI iostream library. You can make use of the `std::streambuf::sbumpc()` function to move the get pointer forward one place. This function returns the character it moved past. These two functions are not exactly equivalent—if the get pointer is already beyond the end, `stossc()` does nothing, and `sbumpc()` returns EOF.

```
istream &extract(istream &is)  
{  
    ...  
    is.rdbuf()->stossc();  
}
```

- `ios::bitalloc()` is no longer available in the ANSI iostream library.
- The filebuf constructors have changed in the ANSI iostream library. The pre-ANSI filebuf class contained three constructors:

```
class filebuf : public streambuf  
{  
    filebuf();  
    filebuf(int fd);  
    filebuf(int fd, char * p, int len);  
    ...  
}
```

In the ANSI iostream library, `filebuf` is a typedef for `basic_filebuf<char>`, and the C++ Working Paper defines one `filebuf` constructor:

```
basic_filebuf();
```

To facilitate backward compatibility, the ANSI iostream library does provide `basic_filebuf(int fd)` as an extension. However, the use of extensions is not portable.

For example, consider the `filebuf` constructors in the following pre-ANSI iostream library program:

7.6 Upgrading from the Class Library to the Standard Library

```
#include <fstream.hxx>

int main () {
    int fd = 1;
    const int BUFLLEN = 1024;
    char buf [BUFLLEN];
    filebuf fb(fd,buf,BUFLLEN);
    filebuf fb1(fd);
    return 0;
}
```

To be strictly ANSI conforming, you would need to recode as follows:

```
filebuf fb(fd,buf,BUFLLEN); as filebuf fb(); and
filebuf fb1(fd); as filebuf fb1();
```

If you want to make use of the ANSI iostream filebuf(fd) extension, you could recode:

```
filebuf fb(fd,buf,BUFLLEN); as filebuf fb(fd); and
filebuf fb1(fd); as filebuf fb1(fd);
```

- The ANSI iostream library contains support for the filebuf::fd() function, which returns the file descriptor for the filebuf object and EOF if the filebuf object is closed as a nonportable extension. This function is not supported under the /STANDARD=STRICT_ANSI compiler mode.
- The following functions are not defined in the ANSI iostream library. They are provided in the ANSI iostream library for backward compatibility only. Their use is not portable.

```
ifstream::ifstream(int fd);
ifstream::ifstream(int fd, char *p, int len)
ofstream::ofstream(int fd);
ofstream::ofstream(int fd, char *p, int len);
fstream::fstream(int fd);
fstream::fstream(int fd, char *p, int len);
```

- The following attach functions, which attach, respectively, a filebuf, fstream, ofstream, and ifstream to a file are not available in the ANSI iostream library:

```
filebuf::attach(int);
fstream::attach(int);
ifstream::attach(int);
ofstream::attach(int);
```

If you do not want to make use of ANSI iostream library extensions, you must recode the use of attach as follows:

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

Change from:

```
#include <fstream.hxx>
#include <stdio.h>
#include <fcntl.h>
int main () {
    int fd;
    fd = open("t27.in",O_RDWR | O_CREAT, 0644);
    ifstream ifs;
    ifs.attach(fd);
    fd = creat("t28.out",0644);
    ofstream ofs;
    ofs.attach(fd);
    return 0;
}
```

To:

```
#include <fstream>
int main () {
    ifstream ifs("t27.in", ios::in | ios::out);
    ofstream ofs("t28.out");
    return 0;
}
```

- The `ios` enumerators for controlling the opening of files, `ios::nocreate` and `ios::noreplace`, are not available in the ANSI `iostream` library.
- The `istream_withassign` and `ostream_withassign` classes are not available in the ANSI `iostream` library.
- In the ANSI `iostream` library `ios_base::width()` applies to all formatted inserters including operator `<<` (`char`). This means that the stream width specified by either the manipulator `setw()` or the `ios_base::width()` member function will apply padding to the next output item even if it is a `char`.

This was not the case in the pre-ANSI `iostream` library, where `width()` applied to all formatted inserters *except* the `char` inserter. The reasons for the change (to allow `ostream::operator<<(char)` to do formatting) are:

1. It allows `operator<<` functions to do formatting consistently.
2. It allows `operator<<(char)` and `put(char)` (formatted and unformatted operations on `char`) to have different functionality.

7.6 Upgrading from the Class Library to the Standard Library

Consider the following example:

```
#ifdef __USE_STD_Iostream
#include <iostream>
#include <iomanip>
#else
#include <iostream.hxx>
#include <iomanip.hxx>
#endif
int main () {
    cout.width(10);
    cout.fill('^');
    cout << 'x' << '\n';
    cout << '[' << setw(10) << 'x' << ']' << endl;
    return 0;
}
```

In the ANSI iostream library the output is:

```
^^^^^^^^^x
[^^^^^^^^^x]
```

In the pre-ANSI iostream library the output is:

```
x
[x]^^^^^^^^^
```

- In the pre-ANSI iostream library, printing signed char * or a unsigned char * printed the address of the string. In the ANSI iostream library the string is printed. Consider the following example:

```
#ifdef __USE_STD_Iostream
#include <iostream>
#else
#include <iostream.hxx>
#endif
int main () {
    char * cs = (char *) "Hello";
    signed char *ss = (signed char *) "world";
    unsigned char *us = (unsigned char *) "again";

    cout << cs << " " << ss << " " << us << endl;
    return 0;
}
```

The output in the ANSI iostream library is:

```
Hello world again
```

The output in the pre-ANSI iostream library is:

```
Hello 0x120001748 0x120001740
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

To obtain output equivalent to the pre-ANSI iostreams, you might do the following:

```
cout << hex << showbase << (long) ss << " "  
      << (long) us << endl;
```

- In the pre-ANSI iostream library printing a signed char prints its integer value. In the ANSI iostream library printing a signed char prints it as a character. Consider the following example:

```
#ifdef __USE_STD_IOSTREAM  
#include <iostream>  
#else  
#include <iostream.hxx>  
#endif  
  
int main () {  
    signed char c = (signed char) 'c';  
    cout << c << endl;  
    return 0;  
}
```

The output in the ANSI iostream library is:

```
c
```

The output in the pre-ANSI iostream library is:

```
99
```

To obtain output equivalent to the pre-ANSI iostreams, you must do the following:

```
cout << (long) c << endl;
```

- In the ANSI iostream library, reading invalid floating point input (where invalid input is caused by no digits following the letter e or E and an optional sign) from a stream sets failbit to flag this error state. In the pre-ANSI iostream library, these type of error conditions might not be detected. Consider this program fragment:

```
double i;  
cin >> i;  
cout << cin.rdstate() << ' ' << i << endl;
```

On the input: 123123e

The output in the ANSI iostream library is:

```
4 2.65261e-314          // failbit set
```

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

The output in the pre-ANSI iostream library is:

```
0 123123          // goodbit set
```

- In the ANSI iostream library, reading integer input (which is truncated as the result of a conversion operation) from a stream sets failbit to flag this overflow condition. In the pre-ANSI iostream library, these types of conditions might not be detected. Consider this program fragment:

```
int i;
cin >> i;
cout << cin.rdstate() << ' ' << i << endl;
```

On the input: 9999999999999999

The output in the ANSI iostream library is:

```
4 1874919423     // failbit set
```

The output in the pre-ANSI iostream library is:

```
0 1874919423     // failbit not set
```

In the ANSI iostream library, reading `-0` from a stream into an unsigned int outputs 0; this was not the case with the pre-ANSI iostream library. Consider the following:

```
unsigned int ui;
cin >> ui;
cout << cin.rdstate() << ' ' << ui << endl;
```

On the input: `-0`

The output in the ANSI iostream library is:

```
0 0
```

- In the ANSI iostream library, the `istream::getline()` function extracts characters and stores them into successive locations of an array whose first element is designated by `s`. If fewer than `n` characters are input, failbit is set. This was not the case in the pre-ANSI iostream library. Consider the following:

```
#include <stdlib.h>
int main()
{
    char buffer[10];
    cin.getline (buffer,10);
    cout << cin.rdstate() << ' ' << buffer << endl;
    return EXIT_SUCCESS;
}
```

With input of: 1234567890

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

The output in the ANSI iostream library is:

```
4 123456789
```

The output in the pre-ANSI iostream library is:

```
0 123456789
```

- When printing addresses, the ANSI library does not print a leading “0x” to indicate a hexadecimal base. The pre-ANSI library did. Consider the following:

```
#include <stdlib.h>
#include <iostream>
int main()
{
    double d;
    int i;

    void *p = (void *) &d;
    int *pi = &i;
    cout << (void *) 0 << ' ' << p << ' ' << pi << endl;
    return EXIT_SUCCESS;
}
```

The output in the ANSI iostream library is:

```
0 11fffe7a0 11fffe798
```

The output in the pre-ANSI iostream library is:

```
0x0 0x11ffffdc40 0x11ffffdc38
```

- `basic_filebuf::setbuf` is a protected member function in the ANSI iostream library. Therefore, the following longer compiles:

```
#include <stdlib.h>
int main() {
    filebuf fb;
    ...
    fb.setbuf(0,0);
    return EXIT_SUCCESS;
}
```

- In the ANSI iostream library, the Standard C++ streams are synchronized with the Standard C streams by default. Calling `sync_with_stdio()` with `false` allows the Standard C++ streams to operate independently of the Standard C streams. In the pre-ANSI iostream library the Standard C++ streams are **not** synchronized with the Standard C streams by default.

7.6 Upgrading from the Class Library to the Standard Library

You notice the consequences of this change if you redirect the output of a program using the Standard C++ streams to a log file by entering the following commands at the DCL prompt:

```
$ define sys$output t.out
$ run program
$ deassign sys$output
```

For example, if you write something like this using ANSI iostreams:

```
#ifndef __USE_STD_Iostream
#define __USE_STD_Iostream
#endif
#include <iostream>
void main () {
    int s = 5;
    cout << "i" << s;
}
```

and if you redirect the output to a log file using the commands shown in the example, the log file contains two records:

```
i
5
```

If you write something like this using pre-ANSI iostreams:

```
#include <iostream.hxx>
void main () {
    int s = 5;
    cout << "i" << s;
}
```

and if you redirect the output to a log file using the commands shown in the example, the log file contains one record: i5.

To obtain the Pre-ANSI iostreams behavior with ANSI iostreams, you can use either of the following workarounds:

- Redirect your output to a file by entering the following commands:

```
$ define/user sys$output t.out
$ run program
```

The output of the log file, t.out, contains one record: i5.

- Recode your program so that the Standard C++ streams operate independently of the Standard C streams. Do this by calling `sync_with_stdio()` with a false argument as follows:

The C++ Standard Library

7.6 Upgrading from the Class Library to the Standard Library

```
#include <stdlib.h>
#ifndef __USE_STD_Iostream
#   define __USE_STD_Iostream
#endif
#include <iostream>
int main () {
    ios_base::sync_with_stdio(false);
    int s = 5;
    cout << "i" << s;
    return EXIT_SUCCESS
}
```

If you now redirect the output to a log file, the log file contains one record: i5.

Using the OpenVMS Debugger

A debugger helps you find run-time errors by letting you observe and interactively manipulate program execution step by step, until you discover where the program functions incorrectly. The OpenVMS Debugger is symbolic, meaning that you can refer to symbolic names for the memory addresses allocated to variables, routines, labels, and so on. You need not use virtual addresses.

The language of the source program you are currently debugging determines the format you use to enter and display data. The language also determines the format used for features, such as comment characters, operators, and operator precedence, which have language-specific settings. However, if you have modules written in another language, you can switch from one language to another during your debugging session.

8.1 Debugging C++ Programs

The OpenVMS Debugger supports the language constructs of C++ and other debugger-supported programming languages. This section describes features specific to debugging C++ programs. For more information on the OpenVMS Debugger, see the *OpenVMS Debugger Manual*.

8.1.1 Compiling and Linking in Preparation for Debugging

To use the debugger, compile and link your program with the `/DEBUG` qualifier on both commands. On the compiler command, the `/DEBUG` qualifier writes into the object module the debug symbol records declared in the program source file. These records make the names of variables and other declared symbols accessible to debugger commands. If your program has several compilation units, make sure you use the `/DEBUG` qualifier to compile each unit you want to debug.

On OpenVMS I64 systems, specifying `/DEBUG` gives you `/DEBUG=(TRACEBACK,SYMBOLS=BRIEF)`, which omits debug information for unused labels and unused types, even when `/NOOPTIMIZE` is specified. This feature results in much smaller object files. To include unused

Using the OpenVMS Debugger

8.1 Debugging C++ Programs

labels and types, specify the `SYMBOLS=NOBRIEF` keyword explicitly (`/DEBUG=(SYMBOLS=NOBRIEF)`).

On OpenVMS Alpha systems, specifying `/DEBUG` gives you `/DEBUG=(TRACEBACK,SYMBOLS)`, which effectively gives you `/DEBUG=(TRACEBACK,SYMBOLS=NOBRIEF)`.

Additionally, use the `/NOOPTIMIZE` qualifier with the compiler command. Optimized code can reduce program size and increase execution speed, but can also create inconsistencies in memory content that adversely affects debugging. Use the default `/OPTIMIZE` qualifier only with programs that have been completely debugged.

8.1.2 Debugger Support

Additionally, compilation with normal (full) optimization will have the following noticeable effects on *OpenVMS Alpha systems*:

- Stepping by line will generally seem to bounce forward and back, due to the effects of code scheduling. The general drift will definitely be forward, but initial experience indicates that the effect will be very close to stepping by instruction.
- Variables that are “split” (so that they are allocated in more than one location during different parts of their lifetimes) are not described at all.

Although not handled quite like normal split variables, formal parameters that are passed in registers share many of the same problems as split variables. Even with the `/NOOPTIMIZE` qualifier, such a parameter often will be copied immediately to a “permanent home” (either on the stack or in some other register) during the routine prolog. The debugger symbol table description of such parameters encodes this permanent home location and *not* the physical register in which the parameter is passed. The end-of-prolog location is recorded in the debugger symbol tables and will be used as the preferred breakpoint location when a breakpoint is set in the context of an appropriately set module (so that symbol table information is available to the debugger).

On the linker command, the `/DEBUG` qualifier incorporates into the executable image all the symbol information contained in the object modules. Using the `/DEBUG` qualifier on the linker command also starts the debugger at run time.

Using the OpenVMS Debugger

8.1 Debugging C++ Programs

Debugger Command-Line Options

The compiler provides a set of debugger options that you can specify to the /DEBUG qualifier on the compiler command line. These options determine the kind of information that the compiler places in the object module for use by the OpenVMS Debugger. These debugger options include using traceback records and using the debugger symbol table. For more information, see the /DEBUG qualifier in Appendix A.

8.1.3 Starting and Ending a Debugging Session

When you enter the DCL run command and specify your executable image file, the OpenVMS Debugger takes control. The debugger displays a message indicating its version, the programming language the source code is written in, and the name of the image file. When the DBG> prompt appears, you can enter debugger commands.

To execute the program, enter the debugger go command. Execution proceeds until the debugger pauses or stops the program (for example, to prompt you for user input, to signal an error, or to inform you that your program completed successfully).

To interrupt the debugging session in progress, press Ctrl/C. The DBG> prompt displays and you can again enter debugger commands.

To end a debugging session, enter the debugger exit command or press Ctrl/Z.

8.1.4 Features Basic to Debugging C++ Programs

This section describes features essential for debugging C++ programs.

8.1.4.1 Determining Language Mode

The OpenVMS Debugger is in C++ language mode when invoked against a main program or routine written in C++. If you are debugging an application with modules written in some language other than C++, you may switch back to C++ language mode by using the command `set language c_plus_plus`.

You can use the `show language` command to determine the language mode set. For example:

```
DBG> show language
language: C_PLUS_PLUS
DBG>
```

Using the OpenVMS Debugger

8.1 Debugging C++ Programs

8.1.4.2 Built-In Operators

This section describes the built-in operators that you can use in debugger commands. The operators in C++ language expressions are as follows:

Symbol	Function	Kind
*	Indirection	Prefix
&	Address of	Prefix
sizeof	size of	Prefix
-	Unary minus (negation)	Prefix
+	Addition	Infix
-	Subtraction	Infix
*	Multiplication	Infix
/	Division	Infix
%	Remainder	Infix
<<	Left shift	Infix
>>	Right shift	Infix
==	Equal to	Infix
!=	Not equal to	Infix
>	Greater than	Infix
>=	Greater than or equal to	Infix
<	Less than	Infix
<=	Less than or equal to	Infix
~ (tilde)	Bit-wise NOT	Prefix
&	Bit-wise AND	Infix
	Bit-wise OR	Infix
^	Bit-wise exclusive OR	Infix
!	Logical NOT	Prefix
&&	Logical AND	Infix
	Logical OR	Infix

Because the exclamation point (!) is an operator, it cannot be used in C++ programs as a comment delimiter. However, to permit debugger log files to be used as debugger input, the debugger still recognizes the exclamation point as a comment delimiter if it is the first nonspace character on a line. In C++ language mode, the debugger accepts a forward slash immediately followed by an asterisk (/*) as the comment delimiter. The comment continues to the end

Using the OpenVMS Debugger

8.1 Debugging C++ Programs

of the current line. A matching asterisk immediately followed by a slash (*) is neither needed nor recognized.

The debugger accepts the asterisk (*) prefix as an indirection operator in both C++ language expressions and debugger address expressions. In address expressions, the asterisk prefix is synonymous to the period (.) prefix or the at sign (@) prefix when the language is set to C++.

To prevent unintended modifications to the program being debugged, the debugger does not support any of the assignment operators in C++ (or any other language). Thus, such operators as =, +=, -=, ++, and -- are not recognized. To alter the contents of a memory location, you must do so with an explicit deposit command.

8.1.4.3 Constructs in Language and Address Expressions

The supported constructs in language and address expressions for C++ are as follows:

Symbol	Construct
[]	Subscripting
. (period)	Structure component selection
->	Pointer dereferencing

8.1.4.4 Data Types

Predefined data types supported in the debugger are as follows:

C++ Data Type	OpenVMS Data Type Name
int, long	Longword Integer
unsigned int, unsigned long	Longword Unsigned
long long	Quadword Integer
unsigned long long	Quadword Unsigned
short int	Word Integer
unsigned short int	Word Unsigned
char	Byte Integer
unsigned char	Byte Unsigned
float	F_Floating (Alpha default), S_Floating (I64 default)

Using the OpenVMS Debugger

8.1 Debugging C++ Programs

C++ Data Type	OpenVMS Data Type Name
double	G_Floating (Alpha default), T_Floating (I64 default), D_Floating
enum	None
struct	None
union	None
class	None
Pointer type	None
Array type	None

Uppercase letters in parentheses represent standard data type mnemonics in the OpenVMS common language environment. For more information, see *OpenVMS Programming Interfaces: Calling a System Routine*.

Supported data types specific to OpenVMS systems are as follows:

C++ Data Type	OpenVMS Data Type Name
__int16	Word Integer
unsigned __int16	Word Unsigned
__int32	Longword Integer
unsigned __int32	Longword Unsigned
__int64	Quadword Integer
unsigned __int64	Quadword Unsigned

8.2 Using the OpenVMS Debugger with C++ Data

This section describes how to use the OpenVMS Debugger with C++ data.

8.2.1 Nonstatic Data Members

This section describes how to refer to data members that are not declared static.

Using the OpenVMS Debugger

8.2 Using the OpenVMS Debugger with C++ Data

8.2.1.1 Noninherited Data Members

To refer to a nonstatic data member that is defined directly in a C++ class (or a struct or union), use its name just as with a C language struct or union member. The following example shows the correct use of a nonstatic data member reference:

```
DBG> examine x.m, p->m
```

8.2.1.2 Inherited Data Members

Currently, debugger support distinguishes nonstatic data members inherited from various base classes by prefixing their names with a sequence of *significant* base class names on the inheritance path to the member, and then the class that the member is declared in. A base class on a path from an object to a member is significant if the base class in question is derived from using multiple inheritance. Thus, a base class is significant if it is mentioned in a base list containing more than one base specifier.

This notation generates the minimum number of base class prefixes necessary to describe the inheritance path to a base class, because it involves naming only those base classes where one must choose where to proceed next when traversing the path. When no multiple inheritance is involved, the reference has the following syntax:

```
CLASS::member
```

Specify the sequence of significant base classes in the order from the object's most derived significant class, to the significant base class closest to the object.

8.2.2 Reference Objects and Reference Members

Because the debugger understands the concept of reference objects and reference members to objects, you can examine a reference object or reference member directly, without dereferencing it as you would for a pointer. To access the values of objects declared with a reference, use the name of the object.

For example, consider the following code:

```
class C {  
public:  
    int &ref_mem;  
    C(int &arg) : ref_mem(arg) {}  
};
```

Using the OpenVMS Debugger

8.2 Using the OpenVMS Debugger with C++ Data

```
main()
{
    auto int obj = 5;
    auto int &ref_obj = obj;
    auto C c(obj);
    obj = 23;
}
...
```

The following sequence shows the correct way to use the debugger to examine the members:

```
break at R8_2_3\main\%LINE 13
13: }
DBG> exam obj, ref_obj
R8_2_3\main\obj:      23
R8_2_3\main\ref_obj: 23
DBG> exam c
R8_2_3\main\c: class C
    ref_mem:      23
DBG> exam c.ref_mem
R8_2_3\main\c.ref_mem: 23
```

8.2.3 Pointers to Members

For Alpha systems compiled with /MODEL=ANSI and for I64 systems, a pointer to member is an offset into a structure.

Consider the following example:

```
struct A {
    int mem0;
};

struct B {
    int mem1;
    int mem2;
};

struct C : public A, public B {
    int mem3;
    int mem4;
};

/* pointer to member initialized with pointer to member
 * address of the same class.
 */
int C::*pmc = &C::mem2;

/* pointer to member initialized with pointer to member
 * address of one of the * base classes. An implicit
 * conversion occurs.
 */
int C::*pmbc = &B::mem2;
```

Using the OpenVMS Debugger 8.2 Using the OpenVMS Debugger with C++ Data

```
extern "C" printf (const char *,...);

main()
{
  C *cinst = new C;
  cinst->*pmc = 7;
  printf("cinst pointer to member value is %d\n",cinst->mem2);
}
```

If you compile this program with the /NOOPTIMIZE/DEBUG qualifiers, from the last line in the program, you can use the pointer to member to display the following information:

```
DBG> set radix hex
DBG> exam *cinst
*EX8_2_4\main\cinst: struct C
  inherit A
    mem0: 00000000
  inherit B
    mem1: 00000000
    mem2: 0000000A
    mem3: 00000000
    mem4: 00000000

DBG> set radix hex

DBG> exa pmc
EX8_2_4\pmc: 00000008

DBG> exam pmbc
EX8_2_4\pmbc: 00000008

DBG> exam cinst
EX8_2_4\main\cinst: 0000000800000090

DBG> exam 080000090+8
0000000800000098: 00000007
```

For the preceding sample program, the above debug sequence examines the pointer to member (`pmc` or `pmbc`) to obtain an offset into the structure, and adds this value to the address of the object (`*cinst`). In our example, this is `*cinst + the value of pmc`.

For Alpha systems compiled with the default object model (`/MODEL=ARM`), a pointer to member involves executing a piece of function-like code, called a `thunk`.

The argument to this function is the address of the base class containing the member. This address is obtained by adding the offset of the start of the base class to the address of the object. This offset adjustment is needed when the pointer to member refers to a multiply inherited base class.

Using the OpenVMS Debugger

8.2 Using the OpenVMS Debugger with C++ Data

A sample debug sequence for the previous program example follows:

```
DBG> set radix hex
DBG> sho sym /full C
type C
  struct (C, 2 components), size: 20 bytes
    inherits: A, size: 4 bytes, offset: 0000000000000000 bytes
              B, size: 8 bytes, offset: 0000000000000004 bytes
    contains the following members:
      mem3 : longword integer, size: 4 bytes, offset: 000000000000000C bytes
      mem4 : longword integer, size: 4 bytes, offset: 0000000000000010 bytes
DBG> exam pmc
EX8_2_4\pmc:    000100D8

DBG> exam cinst
EX8_2_4\main\cinst:    006706F0

DBG> call 000100D8(006706F0+4)
value returned is 006706F8

DBG> exam 006706F8
00000000006706F8:    00000007
```

This debug sequence first obtains the offset to the start of the nested class containing the member pointed to with `show sym /full`. In this case, the offset is 4.

It then examines the pointer to member (`pmc`) and determines the address of the object (`cinst`). In our case, `pmc = 100D8` (thunk) and `cinst = 6706F0`.

Then it calls the thunk, passing the address of the object plus the offset: `CALL 000100D8(006706F0+4)`. This call to the thunk returns the address of the member.

Finally, it examines the member (`006706F8`).

8.2.4 Referencing Entities by Type

To examine and display the value of an object or member by type, use the command `examine/type`. Similarly, you can modify the value of an expression to be deposited to a type you specify by using the command `deposit/type`. With the `/type` qualifier, the syntax for these commands is as follows:

```
deposit/type=(name)
examine/type=(name)
```

The type denoted by *name* must be the name of a variable or data type declared in the program. The `/type` qualifier is particularly useful for referencing C++ objects that have been declared with more than one type.

Using the OpenVMS Debugger

8.3 Using the OpenVMS Debugger with C++ Functions

8.3 Using the OpenVMS Debugger with C++ Functions

This section describes how to reference the various kinds of functions and function arguments.

8.3.1 Referring to Overloaded Functions

You can use the debug SHOW SYMBOL command to see all the overloaded names for a given function. You can set breakpoints on an overloaded function by specifying either the object name and function name followed by the argument types, or by specifying the class name and function name followed by the arguments.

For example, consider the following sample program:

```
extern "C" {int printf(const char *,...);}

class base{
public:
    base(){};
    base(int){};

    ~base(){};

    void base_f1() {printf("called base_f1()\n");}
    void base_f2() {printf("called base_f2()\n");}
    void base_f2(int) {printf("called base_f2(int)\n");}
    void base_f2(char c) {printf("call base_f2(char)\n");}
};

int main()
{
    base b;
    base b1(1);
    b.base_f1();
    b.base_f2(10);
    b.base_f2();
    b.base_f2('c');
}
```

The following debug sequence for the previous sample program shows how to set breakpoints on overloaded symbols and how to list these functions:

Using the OpenVMS Debugger

8.3 Using the OpenVMS Debugger with C++ Functions

```
DBG> s
stepped to EX8_3_1\main\%LINE 20
    20:    base_b1(1);
DBG> set break base::base_f1
DBG> set break base::base_f2
%DEBUG-I-NOTUNQOVR, symbol 'base::base_f2' is overloaded
overloaded name base::base_f2
    instance base::base_f2(char)
    instance base::base_f2(int)
    instance base::base_f2()
%DEBUG-E-REENTER, reenter the command using a more precise pathname
DBG> set break base::base_f2(char)
```

8.3.2 Referring to Destructors

The C++ I64 debugger supports the following format for setting a break on a destructor:

```
DBG> set break stack::~~stack()
DBG> set break stack::~~stack(int)
```

Older (Alpha) debuggers require use of the *%name* syntax:

```
DBG> set break stack::%name'~stack'
```

8.3.3 Referring to Conversions

The set of atomic types are drawn from the following set of names:

void	char	signed_char	unsigned_char	signed_short
unsigned_short	int	signed_int	unsigned_int	signed_long
unsigned_long	float	double	long_double	

Pointer types are named (type)*. Reference types are named (type)&. The types struct, union, class, and enum are named by their tags, and the qualifiers const and volatile precede their types with a space in between. For example:

```
DBG> set break C::int, C::(const S)&
```

Using the OpenVMS Debugger

8.3 Using the OpenVMS Debugger with C++ Functions

8.3.4 Referring to User-Defined Operators

The following operators can be overloaded by user-defined functions:

+	-	*	/	%	^
&		~	!	=	<
>	+=	-=	*=	/=	%=
^=	&=	=	<<	>>	>>=
<<=	==	!=	<=	>=	&&
	++	--	->*	,	->
[]	()	delete	new		

The following example shows the correct use of user-defined function references:

```
DBG> set break stack::%name'operator++'()
```

8.3.5 Referring to Function Arguments

In OpenVMS Debugger referencing, you use `this`, `*this`, and `this->m` as follows:

- All nonstatic member functions have a pointer parameter available named `this`. For example:

```
DBG> examine this
```
- Use `*this` to examine the prefix object that a member function is invoked against. For example:

```
DBG> examine *this
```
- Use the `this` parameter to refer to a data member `m` of the prefix argument to a member function. For example:

```
DBG> examine this->m
```

8.3.6 Calling C++ Member Functions from the Debugger

When calling C++ member functions from the debugger, you cannot make the call using the same syntax that you would use in a C++ source file. You must call the class-qualified member function name with the object as the first argument.

For example:

Using the OpenVMS Debugger

8.3 Using the OpenVMS Debugger with C++ Functions

```
extern "C" void printf(const char *,...);
class C12 {
    int i;
    int j;
public:
    static int sum;
public:
    C12() : i(1), j(2) {}
    void method();
    static int get_sum() {
        printf("called static function get_sum()\n");
        return sum;
    }
};
void C12::method()
{
    i = i + j;
    printf("C12::method called: i=%d, j=%d\n",i,j);
}
int C12::sum = 0;
main()
{
    C12 cinst;
    cinst.method();
    C12::get_sum();
    printf("End of example.\n");
}
```

When you compile this example with `/DEBUG/NOOPT`, you can call the member function with the following command:

```
DBG> call C12::method(cinst)
```

Be aware that when a nonstatic member function is called, the compiler passes an implicit first parameter, the "this" pointer. But, when using the debugger's call instruction, you must explicitly pass this hidden first argument:

```
//Call the nonstatic member function:
DBG> call cinst.method(cinst)
C12::method called: i=3 j=2
value returned is 28
// notice that the following call confuses debug:
DBG> call cinst.method()
%DEBUG-E-MISOPEMIS, misplaced operator or missing operand at 'end of
expression'
```

Using the OpenVMS Debugger

8.3 Using the OpenVMS Debugger with C++ Functions

However, when calling a static member function, there is no implicit this pointer and there function may be called using the class name or the object name:

```
// Call the static function:  
DBG> call C12::get_sum  
called static function get_sum()  
value returned is 0  
DBG> call cinst.get_sum  
called static function get_sum()  
value returned is 0
```

9

Using 64-bit Address Space

This chapter describes 64-bit address support for the HP C++ compiler on OpenVMS Alpha and I64 systems.

The introduction of 64-bit address space in OpenVMS greatly increases the amount of memory available to applications. HP C++ has been enhanced to permit use of this memory. The compiler provides a great deal of flexibility about how this memory can be used. Conceptually, this flexibility can be viewed as four models for development:

- 32-bit development
- 64-bit development
- 32-bit development with long pointers
- 64-bit development with short pointers

In a 32-bit development environment, all pointers are 32-bits long and only 2 gigabytes of address space is available. This is the default and was the only option that was available before this version of the compiler. In a 64-bit development environment, all pointers are 64-bits long and the address space is over a billion gigabytes.

Working in a homogeneous 32-bit or 64-bit environment is the preferred and recommended way to do development. HP C++ for OpenVMS, combined with the C Run-Time library, provide a seamless environment for development. It should be possible for a well written, portable program developed using 32-bit pointers to be recompiled and relinked to use 64-bit pointers.

Because it is not always possible or desirable to work in a homogeneous pointer environment. HP C++ supports mixed pointer sizes, however, it requires greater care by developers. Some contexts where heterogeneous pointer sizes might be used are:

- Memory requirements of 32-bit application exceeds 2 gigabytes
- Access to a legacy 32-bit library is required from a 64-bit application

Using 64-bit Address Space

- The memory foot print of a 64-bit application needs to be reduced

When the memory requirements of a 32-bit application begins to exceed 2 gigabytes, the most straight forward solution is to convert the application to be a 64-bit application. Since practical considerations, like the size of the application or the lack of source code for all parts can prevent this, the alternative approach of isolating the use of 64-bit pointers to a small portion of the application may be preferable. In this situation, development would continue in the 32-bit environment, using long pointers when necessary.

When doing 64-bit development, there are times when it becomes necessary or desirable to use 32-bit pointers. The most common instance is interfacing with a 32-bit library. Another is to save space, because 64-bit pointers consume twice as much memory as 32-bit pointers. In this situation, development could be done in a 64-bit environment, using short pointers when necessary.

Limited empirical evidence suggests that using 32-bit pointers to save space can reduce memory consumption by approximately 25% but at the cost of greater complexity and the creation of potentially unnecessary constraints in the application.

9.1 32-bit Versus 64-bit Development Environment

Besides pointer size, the following components of the development environment determine whether it is a 32- or 64-bit environment:

- Memory allocators
- Libraries

Memory allocators control where in the address space memory is allocated. Memory can be allocated in 32- or 64-bit space independent of the pointer size. The default memory allocator is appropriate for the development environment being used.

Libraries in a 32-bit environment expect pointers to be 32-bits and memory to reside in the 32-bit address space, while libraries in the 64-bit environment expect pointers to be 64-bits. HP C++ for OpenVMS ships with two libraries: one for the 32-bit environment and one for the 64-bit environment. In addition to supporting the 64-bit environment, the second library also supports the new object model referred to as model ANSI.

Caution

When compiling `/POINTER_SIZE=LONG`, the STL template classes (such as `string`, and `set`, `map`) can be used only when `/MODEL=ANSI` is

Using 64-bit Address Space

9.1 32-bit Versus 64-bit Development Environment

specified.

The C Runtime is a single library that supports both environments. See the *HP C Run-Time Library Reference Manual for OpenVMS Systems* for information about how support for both environments was achieved with a single library. See Section 9.6 for a discussion of why it is difficult to produce a single C++ library to support both environments.

9.1.1 Model ANSI

The new ANSI object model allows the compiler to better conform to the ANSI/ISO C++ standard while providing the 64-bit development environment. This object model is specified using the `/MODEL=ANSI` compiler and link options. To build a 64-bit application using the ANSI object model, you enter commands in the following format:

```
$ cxx /model=ansi filename.cxx
$ cxxlink/model=ansi filename
```

Caution

The new ANSI object model is not compatible with the old object model. You must compile and link your entire application with one model or the other.

9.1.2 Memory Allocators

In C++, the primary memory allocator is `new`. Use of the default allocators causes memory to be allocated that is appropriate for the default pointer size for the module (not the current pointer size). Specialized placement-`new` allocators can be used to control where an object is allocated. The header `newext.hxx` contains the following definitions:

```
enum addr32_t {addr_32 };
enum addr64_t {addr_64 };

#pragma pointer_size short
void *operator new(addr32_t, size_t s) { return _malloc32(s); }
void *operator new[](addr32_t, size_t s) { return _malloc32(s); }

#pragma pointer_size long
void *operator new(addr64_t, size_t s) { return _malloc64(s); }
void *operator new[](addr64_t, size_t s) { return _malloc64(s); }
```

Using 64-bit Address Space

9.1 32-bit Versus 64-bit Development Environment

Use of the allocators from the C Run Time is also possible. You can select a specific C allocator by adding a prefix underbar and either 32 or 64 as a suffix.

Function	32-bit	64-bit
malloc	<code>_malloc32</code>	<code>_malloc64</code>
calloc	<code>_calloc32</code>	<code>_calloc64</code>
realloc	<code>_realloc32</code>	<code>_realloc64</code>
strdup	<code>_strdup32</code>	<code>_strdup64</code>

When attempting to mix pointer sizes in your program, distinguish between the concepts of pointer size and memory allocators. The pointer size dictates the maximum amount of address space a pointer can reference, while the allocator controls the where the memory will be allocated.

A library implemented with 64-bit pointers that uses only a 32-bit allocator can with care be used by an application that uses 32-bit pointers. If the library uses a 64-bit allocator, the application cannot reference any pointers returned. To a large extent, it is the memory allocator, not the pointer size, that determines interoperability.

9.1.3 64-bit Pointer Support in the C Run Time Library

In addition to allocators, other functions in the C Run Time Library, such as `strcpy`, are affected by pointer size. As with the allocators, the C++ compiler calls a version of the routine is for the development environment. See the *HP C Run-Time Library Reference Manual for OpenVMS Systems* for more details.

9.2 Qualifiers and Pragmas

The following qualifiers, pragmas, and predefined macros control pointer size:

- `/MODEL=ANSI`
- `/[NO]POINTER_SIZE={LONG | SHORT | 64 | 32}`
- `#pragma pointer_size`
- `#pragma required_pointer_size`
- `#pragma environment cxx_header_defaults`
- `__INITIAL_POINTER_SIZE` predefined macro

9.2.1 The /MODEL=ANSI Qualifier

The /MODEL=ANSI qualifier enables the new ANSI object model. This model implies /POINTER_SIZE=LONG in addition to supporting new C++ constructs that could not be supported in the object object model designed to support the ARM definition of the language. This option must be specified during compilation and linking.

9.2.2 The /POINTER_SIZE Qualifier

The /POINTER_SIZE qualifier lets you specify a value of 64 or 32 (or LONG or SHORT) as the default pointer size within the compilation unit. You can compile one set of modules using 32-bit pointers and another set using 64-bit pointers. Take care when these two separate groups of modules call each other.

The default is /NOPOINTER_SIZE, which has the following effects:

- Disables pointer-size features, such as the ability to use #pragma pointer_size
- Directs the compiler to assume that all pointers are 32-bit pointers

This default represents no change from previous versions of HP C++.

Specifying /POINTER_SIZE with a keyword value (32, 64, SHORT, or LONG) has the following effects:

- Enables processing of #pragma pointer_size.
- Sets the initial default pointer size to 32 or 64, as specified.
- Predefines the preprocessor macro __INITIAL_POINTER_SIZE to 32 or 64, as specified. If /POINTER_SIZE is omitted from the command line, __INITIAL_POINTER_SIZE is 0, which allows you to use #ifdef __INITIAL_POINTER_SIZE to test whether the compiler supports 64-bit pointers.
- For /POINTER_SIZE=64, the HP C RTL name mapping table is changed to select the 64-bit versions of malloc, calloc, and other RTL routines by default.

Use of the /POINTER_SIZE qualifier also influences the processing of HP C RTL header files:

- For those functions that have both 32-bit and 64-bit implementations, specifying /POINTER_SIZE enables function prototypes to access both functions, regardless of the actual value supplied to the qualifier. The value specified to the qualifier determines the default implementation to call during that compilation unit.

Using 64-bit Address Space

9.2 Qualifiers and Pragmas

- Functions that require a second interface to be used with 64-bit pointers reside in the same object libraries and shareable images as their 32-bit counterparts. Because no new object libraries or shareable images are introduced, using 64-bit pointers does not require changes to your link command or link options files.

See the *HP C Run-Time Library Reference Manual for OpenVMS Systems* for more information on the impact of 64-bit pointer support on HP C++ RTL functions.

9.2.3 The `__INITIAL_POINTER_SIZE` Macro

The `__INITIAL_POINTER_SIZE` preprocessor macro is useful for header-file authors to determine:

- Whether the compiler supports 64-bit pointers.
- Whether the application expects to use 64-bit pointers.

Header-file code can then be conditionalized using the following preprocessor directives:

```
#if defined (__INITIAL_POINTER_SIZE) /* Compiler supports 64-bit pointers */
#if __INITIAL_POINTER_SIZE > 0 /* Application uses 64-bit pointers */
#if __INITIAL_POINTER_SIZE == 32 /* Application uses some 64-bit pointers,
but default RTL routines are 32-bit.*/

#if __INITIAL_POINTER_SIZE == 64 /* Application uses 64-bit pointers and
default RTL routines are 64-bit. */
```

9.2.4 Pragmas

The `#pragma pointer_size` and `#pragma required_pointer_size` preprocessor directives can be used to change the pointer size currently in effect within a compilation unit. You can default pointers to 32-bits and then declare specific pointers within the module as 64-bits. In this case, you also need to specifically call the appropriate allocator to obtain memory from the 64-bit memory area.

These pragmas have the following format:

```
#pragma pointer_size keyword
```

```
#pragma required_pointer_size keyword
```

Using 64-bit Address Space 9.2 Qualifiers and Pragas

The *keyword* is one of the following:

{short 32}	32-bit pointer
{long 64}	64-bit pointer
save	Saves the current pointer size
restore	Restores the current pointer size to its last saved state

The `#pragma pointer_size` and `#pragma required_pointer_size` directives work essentially the same way, except that `#pragma required_pointer_size` always takes effect regardless of command-line qualifiers, while `#pragma pointer_size` is in effect only when the `/POINTER_SIZE` command-line qualifier is used.

By changing the command-line qualifier, `#pragma pointer_size` allows a program to be built using 64-bit features as purely as a 32-bit program.

The `#pragma required_pointer_size` is intended for use in header files where interfaces to system data structures must use a specific pointer size regardless of how the program is compiled.

An alternative to controlling the pointer size is `#pragma environment`. This pragma controls all compiler states that include pointer size. This pragma is fully documented in Section 2.1.1.3. The primary change for support of long pointers is the addition of a new **`cxx_header_defaults`** keyword.

This new keyword is similar to the **`header_defaults`** keyword, but differs in the effect on `pointer_size`. With **`header_defaults`**, `pointer_size` is made short, while with **`cxx_header_defaults`**, the `pointer_size` depends on the model being used. When developing in model ANSI, the `pointer_size` is 64 bits; in model ARM (the default), it is 32 bits.

9.3 Determining Pointer Size

The pointer-size qualifiers and pragmas affect only a limited number of constructs in the C++ language itself. At places where the syntax creates a pointer type, the pointer-size context determines the size of that type. Pointer-size context is defined by the most recent pragma (or command-line qualifier) affecting pointer size.

Here are examples of places in the syntax where a pointer type is created:

- The `*` in a declaration or cast:

```
int **p; // Declaration
ip = (int **)i; // Cast
```

Using 64-bit Address Space

9.3 Determining Pointer Size

- The outer (leftmost) brackets [] in a formal parameter imply a *:

```
void foo(int ia[10][20]) {}  
// Means the following:  
void foo(int (*ia)[20]) {}
```

- A function declarator as a formal parameter imply a *:

```
void foo (int func()):  
// Means the following:  
void foo (int (*)() func);
```

- Any formal parameter of array or function type implies a *, even when bound in a typedef:

```
typedef int a_type[10];  
void foo (a_type ia);  
// Means the following:  
void foo (int *ia);
```

9.3.1 Special Cases

The following special cases are not affected by pointer-size context:

- Formal parameters to main are always treated as if they were in a #pragma pointer_size system_default context, which is 32-bit pointers for OpenVMS systems.

For example, regardless of the #pragma pointer_size 64 directive, argv[0] is a 32-bit pointer:

```
#pragma pointer_size 64  
main(int argc, char **argv)  
{ ASSERT(sizeof(argv[0]) == 4); }
```

- A string literal produces a pointer based on the current pointer size when used as an rvalue:

```
#pragma pointer_size 64  
ASSERT(sizeof("x" + 0) == 8);  
#pragma pointer_size 32  
ASSERT(sizeof("x" + 0) == 4);
```

Using 64-bit Address Space

9.3 Determining Pointer Size

- The & operator yields a pointer based on the current pointer size unless it is applied to pointer dereference, in which case it is the size of the dereferenced pointer type:

```
#pragma pointer_size 32
sizeof(&foo) == 32

#pragma pointer_size 64
sizeof(&foo) == 64

sizeof(&s ->next) == sizeof(s)
```

- The size of this pointer depends on the size in effect at the point of the member's signature definition, not on the use of the pointer.

```
class foo {
public:
    void f();
    void f2();
};

#pragma required_pointer_size short
void foo::f()
{ sizeof(this)==4 } // this is short

#pragma required_pointer_size long
void foo::f2()
#pragma required_pointer_size short
{ sizeof(this)==8; } // this is long
```

9.3.2 Mixing Pointer Sizes

An application can use both 32-bit and 64-bit addresses. The following semantics apply when mixing pointers:

- Assignments (including arguments) silently promote a 32-bit pointer rvalue to 64 bits if other type rules are met. Promotion means sign extension.
- A warning is issued for an assignment of a 64-bit rvalue to a 32-bit lvalue (without an explicit cast).
- For purposes of type compatibility, a different size pointer is a different type (for example, when matching a prototype to a definition, or other contexts involving redeclaration), however, overloading is not permitted.
- The debugger knows the difference between pointers of different sizes.

Using 64-bit Address Space

9.4 Header File Considerations

9.4 Header File Considerations

Take note of the following general header-file considerations:

- Header files usually define interfaces with types that must match the layout used in library modules.
- Header files often do not bind “top-level” pointer types. Consider, for example:

```
fprintf(FILE *, const char *, ...);
```

A "FILE * fp;" in a declaration in a different area of source code might be a different size.

- All pointer parameters occupy 64 bits in the calling sequence, so a top-level mismatch of this kind is acceptable if the called function does not lose the high bits internally.
- Routines dealing with pointers to pointers (or data structures containing pointers) cannot be enabled to work simply by passing them both 32-bit and 64-bit pointers. You need separate 32-bit and 64-bit variants of the routine.

Be aware that pointer-size controls are not unique in the way they affect header files; other features that affect data layout have similar impact. For example, most header files should be compiled with 32-bit pointers regardless of pointer-size context. Also, most system header files must be compiled with `member_alignment` regardless of user pragmas or qualifiers.

To address this issue more generally, you can use the `pragma` environment directive to save context and set header defaults at the beginning of each header file, and then to restore context at the end. See Section 2.1.1.3 for a description of `pragma` environment.

For header files that have not yet been upgraded to use `#pragma` environment, the `/POINTER_SIZE=64` qualifier can be difficult to use effectively. For such header files, the compiler automatically applies user-defined prologue and epilogue files before and after the text of the included header file. See Section 9.5 for more information on prologue/epilogue files.

9.5 Prologue/Epilogue Files

HP C++ automatically processes user-supplied prologue and epilogue header files. This feature is an aid to using header files that are not 64-bit aware within an application that is built to exploit 64-bit addressing.

Using 64-bit Address Space 9.5 Prologue/Epilogue Files

9.5.1 Rationale

HP C++ header files typically contain a section at the top that:

1. Saves the current state of the `member_alignment`, `extern_model`, `extern_prefix`, and message pragmas.
2. Sets these pragmas to the default values for the system.

A section at the end of the header file then restores these pragmas to their previously-saved state.

Mixed pointer sizes introduce another kind of state that typically needs to be saved, set, and restored in header files that define fixed 32-bit interfaces to libraries and data structures.

The `#pragma environment` preprocessor directive allows headers to control all compiler states (message suppression, `extern_model`, `member_alignment`, and `pointer_size`) with one directive.

However, for header files that have not yet been upgraded to use `#pragma` environment, the `/POINTER_SIZE=64` qualifier can be difficult to use effectively. In this case, the automatic mechanism to include prologue/epilogue files allows you to protect all of the header files within a single directory (or modules within a single text library). You do this by copying two short files into each directory or library that needs it, without having to edit each header file or library module separately.

In time, you should modify header files to either exploit 64-bit addressing (like the HP C RTL), or to protect themselves with `#pragma` environment. Prologue/epilogue processing can ease this transition.

9.5.2 Using Prologue/Epilogue Files

Prologue/epilogue files are processed in the following way:

1. When the compiler encounters an `#include` preprocessing directive, it determines the location of the file or text library module to be included. It then checks to see if one or both of the two following specially named files or modules exist in the same location as the included file:

```
__DECC_INCLUDE_PROLOGUE.H  
__DECC_INCLUDE_EPILOGUE.H
```

The location is the OpenVMS directory containing the included file or the text library file containing the included module. (In the case of a text library, the `.h` is stripped off.)

Using 64-bit Address Space

9.5 Prologue/Epilogue Files

The directory is the result of using the \$PARSE/\$SEARCH system services with concealed device name logicals translated. Therefore, if an included file is found through a concealed device logical that hides a search list, the check for prologue/epilogue files is still specific to the individual directories making up the search list.

2. If the prologue and epilogue files do exist in the same location as the included file, then the content of each is read into memory.
3. The text of the prologue file is processed *just before* the text of the file specified by the #include.
4. The text of the epilogue file is processed *just after* the text of the file specified by the #include.
5. Subsequent #includes that refer to files from the same location use the saved text from any prologue/epilogue file found there.

The prologue/epilogue files are otherwise treated as if they had been included explicitly: #line directives are generated for them if /PREPROCESS_ONLY output is produced, and they appear as dependencies if /MMS_DEPENDENCY output is produced.

To take advantage of prologue/epilogue processing for included header files, you need to create two files, __DECC_INCLUDE_PROLOGUE.H and __DECC_INCLUDE_EPILOGUE.H, in the same directory as the included file.

Suggested content for a prologue file is:

```
__DECC_INCLUDE_PROLOGUE.H:
#ifdef __PRAGMA_ENVIRONMENT
#pragma environment save
#pragma environment header_defaults
#else
#error "__DECC_INCLUDE_PROLOGUE.H: This compiler does not support
pragma environment"
#endif
```

Suggested content for an epilogue file is:

```
__DECC_INCLUDE_EPILOGUE.H:
#ifdef __PRAGMA_ENVIRONMENT
#pragma __environment restore
#else
#error "__DECC_INCLUDE_EPILOGUE.H: This compiler does not support
pragma environment"
#endif
```

9.6 Avoiding Problems

Consider the following suggestions to avoid problems related to pointer size:

- Write code to work with either 32-bit or 64-bit pointers.
- Do bit manipulation on unsigned int and unsigned __int64, and carefully cast pointers to and from them.
- Heed compile-time warnings, using casts only where you are sure that pointers are not truncated.

9.7 Reasons for Not Using Mixed Pointer Sizes

Although HP C and C++ allow mixing pointer sizes, mixed pointers can cause certain types of error when used incorrectly. Consider the following examples:

- Truncation

```
#pragma pointer_size long
int *y=_malloc64(); // Y is a 64-bit pointer
#pragma pointer_size short
int *x=y; // X is a 32-bit pointer, which results in truncation.
```

- Misread/miswrite

```
int i,j;
#pragma pointer_size short
int *ptr=&i;
int **pptr=&ptr;
#pragma pointer_size long
int **lptr=pptr;

*lptr = &j; // miswrite: 8 bytes write, but points to 4 byte ptr.
ptr = *lptr; // misread: 8 bytes read, but points to 4 byte ptr.
```

Furthermore, the following C++ features discourage the use of mixed pointers:

- Objects can allocate memory. Even if an object is in the 32-bit address space, the data contained in that object might not be.

```
#pragma pointer_size long
class myObject {
  char *myData;
  public:
    myObject() { myData = new char[1000]; }
    ~myObject() { delete[] myData; }
    char *getData() { return myData; }
};
```

Using 64-bit Address Space

9.7 Reasons for Not Using Mixed Pointer Sizes

```
#pragma pointer_size short
myObject *ptr = new myObject(); //32-bit pointer to object in 32 bit space
char *data = ptr->getData(); //32-bit pointer truncated 64 bit pointer
                           to data in 64 bit space
```

- Virtual functions make it difficult to maintain backward compatibility. Consider the following two implementations of an interface called API. One is written in C, the other in C++. With the C implementation, you can add the new entry with the new pointer size in an upwardly compatible way. In C++, you cannot do so because the functions are virtual. Adding a virtual function to a class breaks backward compatibility. Granted, the C++ interface provides polymorphism that is not available in the C interface, but the availability of this feature is one of the reasons why applications are designed using C++.

```
// C implementation of API
void API_f1(int);
#pragma pointer_size short
void API_f2(int *);
#pragma pointer_size long
void API_f2_64(int*);
void API_f3(int);

// C++ implementation of API
class BASE {
public:
    virtual void f1(int);
#pragma pointer_size short
    virtual void f2(int *);
#pragma pointer_size long
    virtual void f2_64(int*);
};
class API : public BASE {
public:
    virtual void f3(int);
}
```

- Polymorphism semantics are difficult to define. It is easy to imagine overloading while working with mixed 32/64 bit pointers when the parameter is a simple pointer: the pointers are simply different types. However, if the pointer is embedded in a structure, how are these structures differentiated? Consider the following code fragment:

```
struct FILE {
    char *buffer;
};

FILE *fopen(const char *, , ,);
int fclose(FILE*);
```

Using 64-bit Address Space

9.7 Reasons for Not Using Mixed Pointer Sizes

It is easy to consider tagging the structure with a flag to indicate whether it is long or short, but it is possible for a structure to have more than one pointer definition. In that case, there could be 2^n different versions of the struct. To avoid these issues, the C++ compiler treats 32 and 64 bit pointers as the same type. If you want to treat pointers as different based on size, use template classes:

```
x.cxx
-----
#include <stdio.h>
#include <iostream>

#if !__INITIAL_POINTER_SIZE
#error this program should be compiled with /POINTER_SIZE qualifier
#endif

template <class T>
class short_pointer {
#pragma pointer_size save
#pragma pointer_size short
    T* ptr;
public:
    short_pointer(T* x) { ptr = x; }
    operator T*() { return ptr; }
    size_t get_ptr_size() { return sizeof(ptr); }
#pragma pointer_size restore
};

template <class T>
class long_pointer {
#pragma pointer_size save
#pragma pointer_size long
    T* ptr;
public:
    long_pointer(T* x) { ptr = x; }
    operator T*() { return ptr; }
    size_t get_ptr_size() { return sizeof(ptr); }
#pragma pointer_size restore
};

template<class T>
void func(short_pointer<T> x) { *x = 5; cout << x.get_ptr_size() << endl; }
template<class T>
void func(long_pointer<T> x) { *x = 5; cout << x.get_ptr_size() << endl; }

int main() {
#pragma pointer_size short
    func(short_pointer<int>((int*)_malloc32(sizeof(int))));
#pragma pointer_size long
    func(long_pointer<int>((int*)_malloc(sizeof(int))));
}
```

Using 64-bit Address Space

9.7 Reasons for Not Using Mixed Pointer Sizes

```
$ pipe cxx/pointer=short x.cxx ; cxxl x.obj ; run x.exe
4
8
$ pipe cxx/pointer=long x.cxx ; cxxl x.obj ; run x.exe
4
8
$
```

A

Compiler Command Qualifiers

This appendix describes the qualifiers available to the CXX command.

Qualifiers indicate special actions to be performed by the compiler or special input file properties. Compiler qualifiers can apply to either the CXX command or to the specification of the file being compiled. When a qualifier follows the CXX command, it applies to all the files listed. When a qualifier follows the file specification, it applies only to the file immediately preceding it.

Table A–1 summarizes CXX qualifiers. Detailed descriptions follow the table.

Table A–1 CXX Command Qualifiers

Command Qualifiers	Defaults
/[NO]ALTERNATIVE_TOKENS	/See text.
/[NO]ANSI_ALIAS	/ANSI_ALIAS
/ARCHITECTURE=option	/ARCHITECTURE=GENERIC
/ASSUME=(option[,...])	See text.
/[NO]CHECK[=[NO]UNINITIALIZED_VARIABLES] (<i>Alpha only</i>)	/NOCHECK
/[NO]COMMENTS=option	/COMMENTS=SPACE
/[NO]DEBUG[=(option[,...])]	/DEBUG=(TRACEBACK,NOSYMBOLS)
/[NO]DEFINE=(identifier[=definition][,...])	/NODEFINE
/[NO]DEFINE=_FORCE_INSTANTIATIONS (<i>Alpha only</i>)	/NODEFINE=_FORCE_INSTANTIATIONS
/[NO]DEFINE=_[NO_]USE_STD_Iostream	/DEFINE=_NO_USE_STD_Iostream
/[NO]DIAGNOSTICS[=file-spec]	/NODIAGNOSTICS
/[NO]DISTINGUISH_NESTED_ENUMS	/NODISTINGUISH_NESTED_ENUMS

(continued on next page)

Compiler Command Qualifiers

Table A–1 (Cont.) CXX Command Qualifiers

Command Qualifiers	Defaults
/ENDIAN=option	/ENDIAN=LITTLE
/[NO]ERROR_LIMIT[=n]	/ERROR_LIMIT=30
/EXCEPTIONS	/See text.
/EXTERN_MODEL=option	/EXTERN_MODEL=RELAXED_REFDEF
/[NO]FIRST_INCLUDE=(file[,...])	/NOFIRST_INCLUDE
/FLOAT=option	/FLOAT=G_FLOAT (<i>Alpha only</i>) /FLOAT=IEEE_FLOAT (<i>I64 only</i>)
/GRANULARITY=option	/GRANULARITY=QUADWORD
/IEEE_MODE[=option]	/IEEE_MODE=FAST (<i>Alpha only</i>) /IEEE_MODE=DENORM_RESULTS (<i>I64 only</i>)
/[NO]IMPLICIT_INCLUDE	/IMPLICIT_INCLUDE
/[NO]INCLUDE_DIRECTORY=(pathname[,...])	/NOINCLUDE_DIRECTORY
/L_DOUBLE_SIZE=option	/L_DOUBLE_SIZE=128
/LIBRARY	See text.
/[NO]LINE_DIRECTIVES	/LINE_DIRECTIVES
/[NO]LIST[=file-spec]	/NOLIST (interactive mode) /LIST (batch mode)
/[NO]MACHINE_CODE	/NOMACHINE_CODE
/[NO]MAIN=POSIX_EXIT	/NOMAIN
/[NO]MEMBER_ALIGNMENT	/MEMBER_ALIGNMENT
/[NO]MMS_DEPENDENCIES=[=(option[,option])]	/NOMMS_DEPENDENCIES
/MODEL={ANSI ARM} (<i>Alpha only</i>)	/MODEL=ARM
/NAMES=(option1,option2)	/NAMES=(UPPERCASE,TRUNCATED)
/NESTED_INCLUDE_DIRECTORY[=option]	/NESTED_INCLUDE_DIRECTORY=INCLUDE_FILE
/[NO]OBJECT[=file-spec]	/OBJECT=.OBJ
/[NO]OPTIMIZE[=(option[,...])]	/OPTIMIZE
/PENDING_INSTANTIATIONS[=n]	/PENDING_INSTANTIATIONS=64
/[NO]POINTER_SIZE[=option]	/NOPOINTER_SIZE
/[NO]PREFIX_LIBRARY_ENTRIES=[(option[,...])]	See text.
/[NO]PREPROCESS_ONLY[=filename]	/NOPREPROCESS_ONLY

(continued on next page)

Compiler Command Qualifiers

Table A–1 (Cont.) CXX Command Qualifiers

Command Qualifiers	Defaults
/PSECT_MODEL=[NO]MULTILANGUAGE	/NOMULTILANGUAGE
/[NO]PURE_CNAME	/PURE_CNAME (/STANDARD=STRICT_ANSI) /NOPURE_CNAME (All other modes)
/[NO]QUIET	/NOQUIET
/REENTRANCY=option	/REENTRANCY=TOLERANT
/REPOSITORY=option	/REPOSITORY=[.CXX_REPOSITORY]
/ROUNDING_MODE=option	/ROUNDING_MODE=NEAREST
/[NO]RTTI	/RTTI
/[NO]SHARE_GLOBALS	/NOSHARE_GLOBALS
/SHOW[=(option[,...])]	/SHOW=(HEADER,SOURCE)
/STANDARD=(option,...)	/STANDARD=RELAXED
/[NO]TEMPLATE_DEFINE[=(option,...)]	See text.
/[NO]UNDEFINE=(identifier[,...])	/NOUNDEFINE
/[NO]UNSIGNED_CHAR	/NOUNSIGNED_CHAR
/[NO]USING_STD	/NOUSING_STD
/[NO]VERSION	/NOVERSION
/[NO]WARNINGS[=(option[,...])]	/WARNINGS
/[NO]XREF[=file-spec] (<i>Alpha only</i>)	/NOXREF

/ALTERNATIVE_TOKENS

/NOALTERNATIVE_TOKENS

Enables use of the following operator keywords and digraphs to generate tokens:

Operator Keyword	Token
and	&&
and_eq	&=
bitand	&
bitor	
compl	~
not	!

Compiler Command Qualifiers

Operator Keyword	Token
not_eq	!=
or	
or_eq	=
xor	^
xor_eq	^=

Digraph	Token
::>]
%:	#
%>	}
<%	{
<:	[

The default is `/NOALTERNATIVE_TOKENS` when compiling with the `/STANDARD=ARM`, `/STANDARD=MS`, or `/STANDARD=RELAXED` option. The default is `/ALTERNATIVE_TOKENS` when compiling with the `/STANDARD=STRICT_ANSI` or `/STANDARD=GNU` option. Specifying `/ALTERNATIVE_TOKENS` also defines the `__ALTERNATIVE_TOKENS` macro.

`/ANSI_ALIAS`

`/ANSI_ALIAS (D)`

`/NOANSI_ALIAS`

Directs the compiler to assume the ANSI/ISO C aliasing rules, which gives it the freedom to generate better optimized code.

`/NOANSI_ALIAS` specifies that any pointer can point to any object, regardless of type. `/ANSI_ALIAS` specifies that pointers to a type T can point to objects of the same type, ignoring type qualifiers such as `const`, `unaligned`, or `volatile`, or whether the object is signed or unsigned. Pointers to a type T can also point to structures, unions, or array members whose type follows the rules above.

The aliasing rules are further explained in Section 3.3, paragraphs 20 and 25, of the ANSI C89 Standard (Section 6.3 of the ISO version, same paragraphs).

`/ARCHITECTURE=option`

Compiler Command Qualifiers

/ARCHITECTURE=GENERIC (D)

Determines the Alpha or Intel processor instruction set to be used by the compiler. The /ARCHITECTURE qualifier uses the same keyword options (keywords) as the /OPTIMIZE=TUNE qualifier.

Where the /OPTIMIZE=TUNE qualifier is primarily used by certain higher-level optimizations for instruction scheduling purposes, the /ARCHITECTURE qualifier determines the type of code instructions generated for the program unit being compiled.

OpenVMS Version 7.1 and subsequent releases provide an operating system kernel that includes an instruction emulator. This emulator allows new instructions, not implemented on the host processor chip, to execute and produce correct results. Applications using emulated instructions will run correctly, but may incur significant software emulation overhead at runtime.

All Alpha processors implement a core set of instructions. Certain Alpha processor versions include additional instruction extensions.

Select one of the /ARCHITECTURE qualifier options shown in the following table.

Option	Usage
GENERIC	Generates code that is appropriate for all processor generations. This is the default.
HOST	Generates code for the processor generation in use on the system being used for compilation. Running programs compiled with this option on other implementations of the Alpha architecture may encounter instruction-emulation overhead.
ITANIUM2 (<i>I64 only</i>)	Generates code for the Intel Itanium 2 processor family. For use on I64 systems only.
EV4 (<i>Alpha only</i>)	Generates code for the 21064, 21064A, 21066, and 21068 implementations of the Alpha architecture. Programs compiled with the EV4 option run without instruction-emulation overhead on all Alpha processors.
EV5 (<i>Alpha only</i>)	Generates code for some 21164 chip implementations of the Alpha architecture that use only the base set of Alpha instructions (no extensions). Programs compiled with the EV5 option will without instruction-emulation overhead on all Alpha processors.

Compiler Command Qualifiers

Option	Usage
EV56 (<i>Alpha only</i>)	Generates code for some 21164 chip implementations that use the byte and word-manipulation instruction extensions of the Alpha architecture. Running programs compiled with the EV56 option might incur emulation overhead on EV4 and EV5 processors, but will still run correctly on OpenVMS Version 7.1 (or higher) systems.
PCA56 (<i>Alpha only</i>)	Generates code for the 21164PC chip implementation that uses the byte- and word-manipulation instruction extensions and multimedia instruction extensions of the Alpha architecture. Programs compiled with the PCA56 option might incur emulation overhead on EV4, EV5, and EV56 processors, but still run correctly on OpenVMS Version 7.1 (or higher) systems.
EV6 (<i>Alpha only</i>)	Generates code for the 21264 implementation of the Alpha architecture.
EV68 (<i>Alpha only</i>)	Generates code for the 21264/EV68 implementation of the Alpha architecture.
EV7 (<i>Alpha only</i>)	Generates code for the EV7 implementation of the Alpha architecture.

See also /OPTIMIZE=TUNE, which is a more typical option. Note that if /ARCHITECTURE is explicitly specified and /OPTIMIZE=TUNE is not, the tuning processor defaults to the architecture processor; for example, /ARCHITECTURE=EV6 implies /OPTIMIZE=TUNE=EV6.

/ASSUME

/ASSUME=(option[,...])

Controls compiler assumptions. You may select the following options:

Option	Usage
[NO]WRITABLE_STRING_LITERALS	Stores string constants in a writable psect. Otherwise, such constants are placed in a nonwriteable psect. The default is NOWRITABLE_STRING_LITERALS.

Compiler Command Qualifiers

Option	Usage
[NO]ACCURACY_SENSITIVE	<p data-bbox="613 646 1232 751">Specifies whether certain code transformations that affect floating-point operations are allowed. These changes may or may not affect the accuracy of the program's results.</p> <p data-bbox="613 762 1232 919">If you specify NOACCURACY_SENSITIVE, the compiler is free to reorder floating-point operations based on algebraic identities (inverses, associativity, and distribution). This allows the compiler to move divide operations outside of loops, which improves performance.</p> <p data-bbox="613 930 1232 1037">The default, ACCURACY_SENSITIVE, directs the compiler to use only certain scalar rules for calculations. This setting can prevent some optimization.</p>

Compiler Command Qualifiers

Option	Usage
[NO]ALIGNED_OBJECTS	<p data-bbox="565 646 1196 842">Controls an optimization for dereferencing pointers. Dereferencing a pointer to a longword- or quadword-aligned object is more efficient than dereferencing a pointer to a byte- or word-aligned object. Therefore, the compiler can generate more optimized code if it makes the assumption that a pointer object of an aligned pointer type does point to an aligned object.</p> <p data-bbox="565 852 1196 1068">Because the compiler determines the alignment of the dereferenced object from the type of the pointer, and the program is allowed to compute a pointer that references an unaligned object (even though the pointer type indicates that it references an aligned object), the compiler must assume that the dereferenced object's alignment matches or exceeds the alignment indicated by the pointer type.</p> <p data-bbox="565 1079 1196 1209">The default, /ASSUME=ALIGNED_OBJECTS, allows the compiler to make such an assumption. With this assumption made, the compiler can generate more efficient code for pointer dereferences of aligned pointer types.</p> <p data-bbox="565 1220 1196 1509">To prevent the compiler from assuming the pointer type's alignment for objects to which it points, use the /ASSUME=NOALIGNED_OBJECTS qualifier. This option causes the compiler to generate longer code sequences to perform indirect load and store operations to avoid hardware alignment faults for arbitrarily aligned addresses. Although /ASSUME=NOALIGNED_OBJECTS might generate less efficient code than the default /ASSUME=ALIGNED_OBJECTS option, by avoiding hardware alignment faults, it speeds the execution of programs that reference unaligned data.</p>

Compiler Command Qualifiers

Option	Usage
[NO]GLOBAL_ARRAY_NEW	<p>Controls whether calls to global array new and delete are generated as specified by ANSI. Pre-ANSI global array new generated calls to operator new(). According to ANSI, use of global array new generates calls to operator new()[]. The GLOBAL_ARRAY_NEW option also defines the macro __GLOBAL_ARRAY_NEW.</p> <p>GLOBAL_ARRAY_NEW generates calls to operator new()[] for global array new expressions such as new int[4]; this is the default when compiling /STANDARD=RELAXED, /STANDARD=STRICT_ANSI, /STANDARD=GNU, and /STANDARD=MS.</p> <p>NOGLOBAL_ARRAY_NEW generates calls to operator new() for global array new expressions such as new int[4]; and preserves compatibility with Version 5.n; this is the default when compiling /STANDARD=ARM.</p>
[NO]HEADER_TYPE_DEFAULT	<p>Controls whether the compiler appends a file extension to a file name. The default is /ASSUME=NOHEADER_TYPE_DEFAULT. To prevent the compiler from appending a file extension to files (such as STL header files that must not have file extensions) use the /ASSUME=NOHEADER_TYPE_DEFAULT qualifier.</p>
[NO]MATH_ERRNO	<p>Controls whether intrinsic code is generated for math functions that set the errno variable. The default is /ASSUME=MATH_ERRNO, which does not allow intrinsic code for such math functions to be generated, even if /OPTIMIZE=INTRINSICS is in effect. Their prototypes and call formats, however, are still checked.</p>

Compiler Command Qualifiers

Option	Usage
[NO]POINTERS_TO_GLOBALS	<p>Controls whether the compiler can safely assume that global variables have not had their addresses taken in code that is not visible to the current compilation.</p> <p>The default is <code>/ASSUME=POINTERS_TO_GLOBALS</code>, which directs the compiler to assume that global variables have had their addresses taken in separately compiled modules and that, in general, any pointer dereference could be accessing the same memory as any global variable. This is often a significant barrier to optimization.</p> <p>While the <code>/ANSI_ALIAS</code> option allows some resolution based on data type, <code>/ASSUME=POINTERS_TO_GLOBALS</code> provides significant additional resolution and improved optimization in many cases.</p> <p>The <code>/ASSUME=NOPOINTERS_TO_GLOBALS</code> option tells the compiler that any global variable accessed through a pointer in the compilation must have had its address taken within that compilation. The compiler can see any code that takes the address of an extern variable. If it does not see the address of the variable being taken, the compiler can assume that no pointer points to the variable.</p> <p>Note that <code>/ASSUME=NOPOINTERS_TO_GLOBALS</code> does not tell the compiler that the compilation never uses pointers to access global variables.</p> <p>Also note that on I64 systems, the <code>NOPOINTERS_TO_GLOBALS</code> option is ignored and should not cause any behavior changes.</p>
[NO]STDNEW	<p>Controls whether calls are generated to the ANSI or pre-ANSI implementation of the operator <code>new()</code>. On memory allocation failure, the ANSI implementation throws <code>std::bad_alloc</code>, while the pre-ANSI implementation returns 0.</p> <p><code>/ASSUME=STDNEW</code> generates calls to the ANSI <code>new()</code> implementation; this is the default when compiling with <code>/STANDARD=RELAXED</code>, <code>/STANDARD=STRICT_ANSI</code>, and <code>/STANDARD=GNU</code>.</p> <p><code>/ASSUME=NOSTDNEW</code> generates calls to the pre-ANSI <code>new()</code> implementation; this is the default when compiling with <code>/STANDARD=ARM</code> and <code>/STANDARD=MS</code>.</p>

Compiler Command Qualifiers

Option	Usage
[NO]TRUSTED_SHORT_ALIGNMENT	<p>Allows the compiler additional assumptions about the alignment of short types that, although thought to be naturally aligned, might cross a quadword boundary.</p> <p>The TRUSTED_SHORT_ALIGNMENT option indicates that the compiler should assume any datatype accessed through a pointer is naturally aligned. This generates the fastest code, but can silently generate the wrong results when an unaligned short object crosses a quadword boundary.</p> <p>Note that on I64 systems, the TRUSTED_SHORT_ALIGNMENT option is ignored and should not cause any behavior changes.</p> <p>The NOTRUSTED_SHORT_ALIGNMENT tells the compiler that short objects might not be naturally aligned. The compiler generates slightly larger (and slower) code that gives the correct result, regardless of the actual alignment of the data. This is the default.</p> <p>Note that the NOTRUSTED_SHORT_ALIGNMENT option does not override the <code>__unaligned</code> type qualifier or the <code>/ASSUME=NOALIGNED_OBJECTS</code> option.</p>
[NO]WHOLE_PROGRAM	<p>Tells the compiler that except for well-behaved library routines, the whole program consists only of the single object module being produced by this compilation. The optimizations enabled by <code>/ASSUME=WHOLE_PROGRAM</code> include all those enabled by <code>/ASSUME=NOPOINTERS_TO_GLOBS</code> and possibly other optimizations.</p> <p>Note that on I64 systems, the WHOLE_PROGRAM option is ignored and should not cause any behavior changes.</p> <p>The default is <code>/ASSUME=NOWHOLE_PROGRAM</code>.</p>

/CHECK

/CHECK=[([NO]UNINITIALIZED_VARIABLES)] *(Alpha only)*

/NOCHECK (D)

Use this qualifier as a debugging aid.

Use `/CHECK=UNINITIALIZED_VARIABLES` to initialize all automatic variables to the value `0x7ff580057ff58005`. This value is a floating NaN and, if used, causes a floating-point trap. If used as a pointer, this value is likely to cause an ACCVIO.

Note that on I64 systems, `/CHECK=UNINITIALIZED_VARIABLES` emits a warning and is ignored.

Compiler Command Qualifiers

/COMMENTS

/COMMENTS[=option]

/COMMENTS=SPACE (D)

/NOCOMMENTS

Specifies whether comments appear in preprocessor output files. If comments do not appear, this qualifier specifies what replaces them. The options are:

Option	Usage
AS_IS	Specifies that the comment appear in the output file. This is the default if you use the /COMMENTS qualifier without specifying an option.
SPACE	Specifies that a single space replaces the comment in the output file. This is the default if you do not specify the /COMMENTS qualifier at all.

Specifying /NOCOMMENTS tells the preprocessor that nothing replaces the comment in the output file. This may result in inadvertent token pasting.

The preprocessor may replace a comment at the end of a line or replace a line by itself with nothing, even if you specify /COMMENTS=SPACE. Specifying /COMMENTS=SPACE cannot change the meaning of the program.

/DEBUG

/DEBUG[=(option[,...])]

/DEBUG=(TRACEBACK,NOSYMBOLS) (D)

/NODEBUG

Requests that information be included in the object module for use with the OpenVMS Debugger. You can select the following options:

Option	Usage
ALL	Includes all possible debugging information. /DEBUG=ALL is equivalent to /DEBUG=(TRACEBACK,SYMBOLS), which on I64 systems is equivalent to /DEBUG=(TRACEBACK,SYMBOLS=NOBRIEF).
NONE	Excludes all debugging information. This option is equivalent to specifying /NODEBUG, which is equivalent to /DEBUG=(NOTRACEBACK,NOSYMBOLS).
NOSYMBOLS	Turns off symbol generation
SYMBOLS	Generates symbol-table records. On I64 systems, /DEBUG=SYMBOLS is equivalent to /DEBUG=SYMBOLS=BRIEF. On Alpha systems, /DEBUG=SYMBOLS is effectively equivalent to /DEBUG=NOBRIEF.

Compiler Command Qualifiers

Option	Usage
<code>SYMBOLS=BRIEF</code> <i>(I64 only)</i>	Generates debug information with unreferenced labels and types pruned out to produce smaller object sizes. On Alpha systems, BRIEF is ignored.
<code>SYMBOLS=NOBRIEF</code> <i>(I64 only)</i>	Generates complete debug information. On Alpha systems, the NOBRIEF keyword is ignored, but you still get complete debug information.
<code>NOTRACEBACK</code>	Excludes traceback records. This option is equivalent to specifying /NODEBUG and is used to avoid generating extraneous information from thoroughly debugged program modules.
<code>TRACEBACK</code>	Includes only traceback records. This option is the default if you do not specify the /DEBUG qualifier on the command line.

On Alpha systems /DEBUG is equivalent to /DEBUG=(TRACEBACK,SYMBOLS).

On I64 systems /DEBUG is equivalent to /DEBUG=(TRACEBACK,SYMBOLS), which is equivalent to /DEBUG=(TRACEBACK,SYMBOLS=BRIEF).

/DEFINE

/DEFINE=(identifier[=definition][,...])

/NODEFINE (D)

Performs the same function as the #define preprocessor directive. That is, /DEFINE defines a token string or macro to be substituted for every occurrence of a given identifier in the program.

DCL converts all input to uppercase unless it is enclosed in quotation marks.

The simplest form of a /DEFINE definition is as follows:

```
/DEFINE=true
```

This results in a definition like the one that would result from the following definition:

```
#define TRUE 1
```

When more than one /DEFINE is present on the CXX command line or in a single compilation unit, only the last /DEFINE is used.

When both /DEFINE and /UNDEFINE are present on a command line, /DEFINE is evaluated before /UNDEFINE.

Compiler Command Qualifiers

/DEFINE=__FORCE_INSTANTIATIONS *(Alpha only)*

/NODEFINE=__FORCE_INSTANTIATIONS (D)

Forces the standard library template preinstantiations to be created in the user's repository. Normally these instantiations are suppressed because the library already contains them.

On I64 systems, defining `__FORCE_INSTANTIATIONS` has no effect.

/DEFINE=__[NO_]USE_STD_Iostream

/DEFINE=__NO_USE_STD_Iostream (D)

Use or do not use the standard iostreams. Specifying `/DEFINE=__USE_STD_Iostream` forces the inclusion of the ANSI standard version of the iostream header file. This is the default in `STRICT_ANSI` mode. Otherwise, the pre-standard AT&T-compatible version of iostreams is used.

/DIAGNOSTICS

/DIAGNOSTICS[=file-spec]

/NODIAGNOSTICS (D)

Creates a file containing compiler diagnostic messages. The default file extension for a diagnostics file is `.DIA`. The diagnostics file is used with the DEC Language-Sensitive Editor (LSE). To display a diagnostics file, enter the command `REVIEW/FILE=file-spec` while in LSE.

/DISTINGUISH_NESTED_ENUMS

/NODISTINGUISH_NESTED_ENUMS (D)

Causes the compiler, when forming a mangled name, to include the name of any enclosing classes within which an enum is nested, thereby preventing different functions from receiving the same mangled name.

This qualifier has no meaning on I64 systems because it modifies the behavior of programs compiled with `/MODEL=ARM`, and that model is not supported on I64 systems.

/ENDIAN

/ENDIAN={BIG | LITTLE}

/ENDIAN=LITTLE (D)

Controls whether big or little endian ordering of bytes is carried out in character constants.

/ERROR_LIMIT

/ERROR_LIMIT[=number]

/ERROR_LIMIT=30 (D)

/NOERROR_LIMIT

Limits the number of error-level diagnostic messages that are acceptable during program compilation. Compilation terminates when the limit (number)

Compiler Command Qualifiers

is exceeded. `/NOERROR_LIMIT` specifies that there is no limit on error messages.

The default is `/ERROR_LIMIT=30`, which specifies that compilation terminates after issuing 30 error messages.

`/EXCEPTIONS`

`/EXCEPTIONS=CLEANUP (D)`

`/EXCEPTIONS=NOCLEANUP` *(Alpha only)*

`/EXCEPTIONS=EXPLICIT (D)`

`/EXCEPTIONS=IMPLICIT` *(Alpha only)*

`/NOEXCEPTIONS`

Controls whether support for C++ exceptions is enabled or disabled. C++ exceptions are enabled by default (equivalent to `/EXCEPTIONS=CLEANUP`). When C++ exceptions are enabled, the compiler generates code for throw expressions, try blocks, and catch statements. The compiler also generates special code for main programs so that the `terminate()` routine is called for unhandled exceptions. You can select from the following options:

CLEANUP	Generate cleanup code for automatic objects. When an exception is handled at run-time and control passes from a throw-point to a handler, call the destructors for all automatic objects that were constructed because the try-block containing the handler was entered.
NOCLEANUP <i>(Alpha only)</i>	Do not generate cleanup code. Using this option can reduce the size of your executable when you want to throw and handle exceptions and cleanup of automatic objects during exception processing is not important for your application. The NOCLEANUP option is ignored on I64 systems.
EXPLICIT	Tells the compiler to assume the standard C++ rules about exceptions. Catch clauses can catch only those exceptions resulting from the evaluation of a throw expression within the body of the catch clause's try block or from within a procedure called from within the catch clause's try block.

Compiler Command Qualifiers

IMPLICIT
(Alpha only)

On Alpha systems, tells the compiler that an exception might be thrown at any time the program is executing code within the body of the try block. These exceptions might be the result of a throw expression, hardware errors, or software errors (such as dereferencing an invalid pointer).

Specifying `/EXCEPTIONS=IMPLICIT` seriously interferes with the compiler's ability to optimize code. When the compiler optimizes a function, it must ensure that the values of all variables after an exception is caught remain the same as they were at the point where the exception was thrown. The optimizer is therefore limited in its ability to rearrange stores and expressions that might cause an exception to be thrown.

With `/EXCEPTIONS=EXPLICIT`, this is not a serious restriction, because the compiler cannot rearrange stores and expressions around the code that explicitly raises an exception. In implicit exception mode, however, almost any code has the potential to cause an exception to be thrown, thereby dramatically reducing the optimizer's ability to rearrange code.

Also, if the compiler can determine that no throw expressions occur within a try block, it can eliminate the exception handling overhead the try block introduces, including all code within the catch clauses associated with the try block. Because no exceptions can occur during the execution of the code within the try block, no code within the catch clauses can ever be executed. The compiler cannot do this with `/EXCEPTIONS=IMPLICIT`.

Use `/EXCEPTIONS=IMPLICIT` if your program converts signals to C++ exceptions by calling `cx1$set_condition(cxx_exception)`. Failure to do so may result in your code not catching the exceptions produced by signals.

For example, consider the following routine:

```
void f(int *p) {
    try {
        *p = 2;
    } catch (...) {
        ...
    }
}
```

Failure to compile the routine with `/EXCEPTIONS=IMPLICIT` may result in a failure to catch the exception generated by the SIGBUS signal that occurs if `p` is 0. This is because the compiler sees that there are no throws nor procedure calls within `f` and therefore optimizes away the try block leaving:

```
void f(int *p) {
    *p = 2;
}
```

Compiler Command Qualifiers

Except for those OpenVMS conditions that result in the delivery of signals, if you raise a condition explicitly using a mechanism such as LIB\$SIGNAL, you may use /EXCEPTIONS=EXPLICIT.

The /NOEXCEPTIONS qualifier disables C++ exceptions as follows:

1. The compiler issues errors for throw expressions, try blocks, and catch statements, but might generate code for these constructs.
2. On Alpha systems, the compiler does not generate cleanup code for automatic objects.
3. The compiler does not generate special code for main programs so that the terminate() function is called for unhandled exceptions.

The /EXCEPTIONS qualifier defines the macro __EXCEPTIONS.

/EXTERN_MODEL

/EXTERN_MODEL=option

/EXTERN_MODEL=RELAXED_REFDEF (D)

In conjunction with the /SHARE_GLOBALS qualifier, controls the initial extern model of the compiler. Conceptually, the compiler behaves as if the first line of the program being compiled was a #pragma extern_model directive with the model and psect name, if any, specified by the /EXTERN_MODEL qualifier and with the SHR or NOSHR keyword specified by the /SHARE_GLOBALS qualifier.

For example, assume the command line contains the following qualifier:

```
/EXTERN_MODEL=STRICT_REFDEF="MYDATA"/NOSHARE
```

The compiler acts as if the program began with the following line:

```
#pragma extern_model strict_refdef "MYDATA" noshr
```

For more information on the various models, see Section 2.1.1.4.

The /EXTERN_MODEL qualifier takes the following options, which have the same meaning as for the #pragma extern_model directive:

```
COMMON_BLOCK  
RELAXED_REFDEF  
STRICT_REFDEF=["NAME"]  
GLOBALVALUE
```

The default is RELAXED_REFDEF.

Compiler Command Qualifiers

/FIRST_INCLUDE

/FIRST_INCLUDE=(file[, ...])

/NOFIRST_INCLUDE (D)

Includes the specified files before any source files. This qualifier corresponds to the Tru64 UNIX `-FI` switch.

When `/FIRST_INCLUDE=file` is specified, `file` is included in the source as if the line before the first line of the source were:

```
#include "file"
```

If more than one file is specified, the files are included in their order of appearance on the command line.

This qualifier is useful if you have command lines to pass to the C compiler that are exceeding the DCL command-line length limit. Using the `/FIRST_INCLUDE` qualifier can help solve this problem by replacing lengthy `/DEFINE` and `/WARNINGS` qualifiers with `#define` and `#pragma message` preprocessor directives placed in a `/FIRST_INCLUDE` file.

The default is `/NOFIRST_INCLUDE`.

/FLOAT

/FLOAT=option

/FLOAT=G_FLOAT (*Alpha only*) **(D)**

/FLOAT=IEEE_FLOAT (*I64 only*) **(D)**

Controls the format of floating-point variables. The options are:

Option	Usage
D_FLOAT	double variables are represented in VAX D_floating format. float variables are represented in VAX F_floating format. The <code>__D_FLOAT</code> macro is predefined.
G_FLOAT	double variables are represented in VAX G_floating format. float variables are represented in VAX F_floating format. The <code>__G_FLOAT</code> macro is predefined.
IEEE_FLOAT	float and double variables are represented in IEEE floating-point format (S_float and T_float, respectively). The <code>__IEEE_FLOAT</code> macro is predefined. Use the <code>/IEEE_MODE</code> qualifier for controlling the handling of IEEE exceptional values.

On Alpha systems, the default is `/FLOAT=G_FLOAT`.

On I64 systems, the default is `/FLOAT=IEEE_FLOAT`.

See Section 4.1.6 for additional information on floating-point representation on I64 and Alpha systems.

Compiler Command Qualifiers

/GRANULARITY
/GRANULARITY=option
/GRANULARITY=QUADWORD (D)

Controls the size of shared data in memory that can be safely accessed from different threads. The possible size values are BYTE, LONGWORD, and QUADWORD.

Specifying BYTE allows single bytes to be accessed from different threads sharing data in memory without corrupting surrounding bytes. This option will slow runtime performance.

Specifying LONGWORD allows naturally aligned 4-byte longwords to be accessed safely from different threads sharing data in memory. Accessing data items of 3 bytes or less, or unaligned data, may result in data items written from multiple threads being inconsistently updated.

Specifying QUADWORD allows naturally aligned 8-byte quadwords to be accessed safely from different threads sharing data in memory. Accessing data items of 7 bytes or less, or unaligned data, might result in data items written from multiple threads being inconsistently updated. This is the default.

/IEEE_MODE
/IEEE_MODE=option
/IEEE_MODE=FAST (D) (*Alpha only*)
/IEEE_MODE=DENORM_RESULTS (D) (*I64 only*)

Selects the IEEE floating-point mode to be used if the /FLOAT=IEEE_FLOAT qualifier is specified. The options are:

Option	Usage
FAST	During program execution, only finite values (no infinities, NaNs, or denorms) are created. Underflows and denormal values are flushed to zero. Exceptional conditions, such as floating-point overflow, divide-by-zero, or use of an IEEE exceptional operand are fatal.
UNDERFLOW_TO_ZERO	Generate infinities and NaNs. Flush denormalized results and underflow to zero without exceptions.
DENORM_RESULTS	Same as the UNDERFLOW_TO_ZERO option, except that denorms are generated.

Compiler Command Qualifiers

Option	Usage
INEXACT	Same as the DENORM_RESULTS option, except that inexact values are trapped. This is the slowest mode, and is not appropriate for any sort of general-purpose computations.

On Alpha systems, the default is `/IEEE_MODE=FAST`.

On I64 systems, the default is `/IEEE_MODE=DENORM_RESULTS`.

The INFINITY and NAN macros defined in `<math.h>` are available to programs compiled with `/FLOAT=IEEE` and `/IEEE_MODE={anything other than FAST}`.

On Alpha systems, the `/IEEE_MODE` qualifier generally has its greatest effect on the generated code of a compilation. When calls are made between functions compiled with different `/IEEE_MODE` qualifiers, each function produces the `/IEEE_MODE` behavior with which it was compiled.

On I64 systems, the `/IEEE_MODE` qualifier primarily affects only the setting of a hardware register at program startup. In general, the `/IEEE_MODE` behavior for a given function is controlled by the `/IEEE_MODE` option specified on the compilation that produced the main program: the startup code for the main program sets the hardware register according to the command-line qualifiers used to compile the main program.

When applied to a compilation that does not contain a main program, the `/IEEE_MODE` qualifier does have some effect: it might affect the evaluation of floating-point constant expressions, and it is used to set the EXCEPTION_MODE used by the math library for calls from that compilation. But the qualifier has no effect on the exceptional behavior of floating-point calculations generated as inline code for that compilation. Therefore, if floating-point exceptional behavior is important to an application, all of its compilations, including the one containing the main program, should be compiled with the same `/IEEE_MODE` setting.

Even on Alpha systems, the particular setting of `/IEEE_MODE=UNDERFLOW_TO_ZERO` has this characteristic: its primary effect requires the setting of a runtime status register, and so it needs to be specified on the compilation containing the main program in order to be effective in other compilations.

Also see the `/FLOAT` qualifier.

Compiler Command Qualifiers

/IMPLICIT_INCLUDE

/IMPLICIT_INCLUDE (D)

/NOIMPLICIT_INCLUDE

/IMPLICIT_INCLUDE enables inclusion of source files as a method of finding definitions of template entities. By default it is enabled for normal compilation, and disabled for preprocessing only. The search rules for finding template definition files is the same as for include files.

/NOIMPLICIT_INCLUDE disables inclusion of source files as a method of finding definitions of template entities. You might want to use this option in conjunction with the **/STANDARD=MS** command line option, to match more closely the behavior on Microsoft C++.

/INCLUDE_DIRECTORY

/INCLUDE_DIRECTORY=(place[,...])

/NOINCLUDE_DIRECTORY (D)

Provides an additional level of search for user-defined include files. Each *pathname* argument can be either a logical name or a legal UNIX style directory in a quoted string. The default is **/NOINCLUDE_DIRECTORY**.

The **/INCLUDE_DIRECTORY** qualifier provides functionality similar to the **-I** option of the **cxx** command on Tru64 UNIX systems. This qualifier allows you to specify additional locations to search for files to include. Putting an empty string in the specification prevents the compiler from searching any of the locations it normally searches but directs it to search *only* in locations you identify explicitly on the command line with the **/INCLUDE_DIRECTORY** and **/LIBRARY** qualifiers (or by way of the specification of the primary source file, depending on the **/NESTED_INCLUDE_DIRECTORY** qualifier).

The basic order for searching depends on the form of the header name (after macro expansion), with additional aspects controlled by other command line qualifiers as well as the presence or absence of logical name definitions. The valid possibilities for names are as follows:

- Enclosed in quotes. For example: "stdio.h"
- Enclosed in angle brackets. For example: <stdio.h>

Unless otherwise defined, searching a location means that the compiler uses the string specifying the location as the default file specification in a call to an RMS system service (that is, a **\$SEARCH/\$PARSE**) with a primary file specification consisting of the name in the **#include** (without enclosing delimiters). The search terminates successfully as soon as a file can be opened for reading.

Compiler Command Qualifiers

Specifying a null string in the `/INCLUDE` qualifier causes the compiler to do a non-standard search. This search path is as follows:

1. The current directory (quoted form only)
2. Any directories specified in the `/INCLUDE` qualifier
3. The directory of the primary input file
4. Text libraries specified on the command line using `/LIBRARY`

For standard searches, the search order is as follows:

1. Search the current directory (directory of the source being processed).
If angle-bracket form, search only if no directories are specified with `/INCLUDE_DIRECTORY`.
2. Search the locations specified in the `/INCLUDE_DIRECTORY` qualifier (if any).
3. If `CXX$SYSTEM_INCLUDE` is defined as a logical name, search `CXX$SYSTEM_INCLUDE:.HXX` or just `CXX$SYSTEM_INCLUDE:.`, depending on the qualifier `/ASSUME=NOHEADER_TYPE_DEFAULT`. If nothing is found, go to step 6.
4. If `CXX$LIBRARY_INCLUDE` is defined as a logical name, `CXX$LIBRARY_INCLUDE:.HXX` or `CXX$LIBRARY_INCLUDE:.`, depending on the qualifier `/ASSUME=NOHEADER_TYPE_DEFAULT`. If nothing is found, go to step 6.
5. If `/ASSUME=HEADER_TYPE_DEFAULT` is not specified, search the default list of locations for plain-text copies of compiler header files as follows:

```
SYS$COMMON:[CXX$LIB.INCLUDE.CXXL$ANSI_DEF]  
SYS$COMMON:[CXX$LIB.INCLUDE.DECC$RTLDEF_HXX].HXX  
SYS$COMMON:[DECC$LIB.INCLUDE.DECC$RTLDEF].H  
SYS$COMMON:[DECC$LIB.INCLUDE.SYS$STARLET_C].H
```

If `/ASSUME=HEADER_TYPE_DEFAULT` is specified, search the default list of locations for plain-text copies of compiler header files as follows:

```
SYS$COMMON:[CXX$LIB.INCLUDE.DECC$RTLDEF_HXX].HXX  
SYS$COMMON:[DECC$LIB.INCLUDE.DECC$RTLDEF].H  
SYS$COMMON:[DECC$LIB.INCLUDE.SYS$STARLET_C].H  
SYS$COMMON:[CXX$LIB.INCLUDE.CXXL$ANSI_DEF]
```

6. Search the directory of the primary input file.

Compiler Command Qualifiers

7. If quoted form, and CXX\$USER_INCLUDE is defined as a logical name, search CXX\$USER_INCLUDE:.HXX or CXX\$USER_INCLUDE:., depending on the /ASSUME=NOHEADER_TYPE_DEFAULT qualifier.
8. Search the text libraries. Extract the simple file name and file type from the #include specification, and use them to determine a module name for each text library. There are three forms of module names used by the compiler:

1. type stripped:

The file type will be removed from the include file specification to form a library module name. Examples:

#include "foo.h"	Module name "FOO"
#include "foo"	Module name "FOO"
#include "foo"	Module name "FOO"

2. type required:

The file type must be a part of the file name. Examples:

#include "foo.h"	Module name "FOO.H"
#include "foo"	Module name "FOO."
#include "foo"	Module name "FOO."

3. type optional:

First an attempt is made to find a module with the type included in the module name. If this is unsuccessful, an attempt is made with the type stripped from the module name. If this is unsuccessful, the search moves on to the next library.

If /ASSUME=HEADER_TYPE_DEFAULT is specified, the following text libraries are searched in this order:

- Libraries specified on the command line with the /LIBRARY qualifier (all files, type stripped)
- CXX\$TEXT_LIBRARY (all files, type stripped)
- DECC\$RTLDEF (H files and unspecified files, type stripped)
- SY\$STARLET_C (all files, type stripped)
- CXXL\$ANSI_DEF (unspecified files, type stripped)

Otherwise, these text libraries are searched in this order:

- Libraries specified on the command line with the /LIBRARY qualifier (all files, type optional)
- CXX\$TEXT_LIBRARY (all files, type optional)
- CXXL\$ANSI_DEF (all files, type required)

Compiler Command Qualifiers

DECC\$RTLDEF (H files and unspecified files, type stripped)
SYS\$STARLET_C (all files, type stripped)

Two text library search examples (stop when something is found):

Example 1

```
#include "foo"
```

1. For each library specified via the /LIBRARY qualifier:
 - Look for "FOO."
 - Look for "FOO"
2. Look for "FOO." in CXX\$TEXT_LIBRARY
3. Look for "FOO" in CXX\$TEXT_LIBRARY
4. Look for "FOO." in CXXL\$ANSI_DEF (Do not look for "FOO" because the type is required as part of the module name)
5. Look for "FOO" in DECC\$RTLDEF (not "FOO." because the type must not be part of the module name)
6. Look for "FOO" in SYS\$STARLET_C (not "FOO." because the type must not be part of the module name)

Example 2

```
#include "foo.h"
```

1. For each library specified via the /LIBRARY qualifier:
 - Look for "FOO.H"
 - Look for "FOO"
2. Look for "FOO.H" in CXX\$TEXT_LIBRARY
3. Look for "FOO" in CXX\$TEXT_LIBRARY
4. Look for "FOO.H" in CXXL\$ANSI_DEF (Do not look for "FOO" because the type is required as part of the module name)
5. Look for "FOO" in DECC\$RTLDEF (not "FOO.H" because the type must not be part of the module name)
6. Look for "FOO" in SYS\$STARLET_C (not "FOO.H" because the type must not be part of the module name)
7. If neither CXX\$LIBRARY_INCLUDE nor CXX\$SYSTEM_INCLUDE is defined as a logical name, then search SYS\$LIBRARY:.HXX.

Compiler Command Qualifiers

/L_DOUBLE_SIZE

/L_DOUBLE_SIZE=option

/L_DOUBLE_SIZE=128 (D)

Determines how the compiler interprets the long double type. The qualifier options are 64 and 128.

Specifying `/L_DOUBLE_SIZE=64` treats all long double references as `G_FLOAT`, `D_FLOAT`, or `T_FLOAT`, depending on the value of the `/FLOAT` qualifier. Specifying `/L_DOUBLE_SIZE=64` also defines the macro `__X_FLOAT=0`.

Note: The `/L_DOUBLE_SIZE=64` option is not available on I64 systems. If it is specified, the compiler issues a warning message and uses `/L_DOUBLE_SIZE=128`.

Specifying `/L_DOUBLE_SIZE=128` treats all long double references as `X_FLOAT`. The `/L_DOUBLE_SIZE=128` option also defines the macro `__X_FLOAT=1`. This is the default.

/LIBRARY

Indicates that the associated input file is a text library containing source text modules specified in `#include` directives. The compiler searches the specified library for all `#include` module names that are not enclosed in angle brackets or quotation marks. The name of the library must be concatenated with the file specification using a plus sign. For example: `CXX DATAB/LIBRARY+APPLICATION`

/LINE_DIRECTIVES

/LINE_DIRECTIVES (D)

/NOLINE_DIRECTIVES

Controls whether `#line` directives appear in preprocessed output files.

/LIST

/LIST[=file-spec] (Batch default)

/NOLIST (Interactive default)

Controls whether a listing file is produced. The default output file extension is `.LIS`.

/MACHINE_CODE

/NOMACHINE_CODE (D)

Controls whether the listing produced by the compiler includes the machine-language code generated during the compilation. If you use this qualifier you also need to use the `/LIST` qualifier. On Alpha systems, machine-language code is not added to the listing file when object-file generation is disabled (using the `/NOOBJECT` qualifier).

Compiler Command Qualifiers

/MAIN=POSIX_EXIT

/MAIN=POSIX_EXIT

/NOMAIN (D)

Directs the compiler to call `__posix_exit` instead of `exit` when returning from `main`.

/MEMBER_ALIGNMENT

/MEMBER_ALIGNMENT (D)

/NOMEMBER_ALIGNMENT

Directs the compiler to naturally align data structure members. This means that data structure members are aligned on the next boundary appropriate to the type of the member, rather than on the next byte. For instance, a long variable member is aligned on the next longword boundary; a short variable member is aligned on the next word boundary.

Any use of the `#pragma member_alignment` or `#pragma nomember_alignment` directives within the source code overrides the setting established by this qualifier. Specifying `/NOMEMBER_ALIGNMENT` causes data structure members to be byte-aligned (with the exception of bit-field members).

/MMS_DEPENDENCIES

/MMS_DEPENDENCIES[=(option[,option])]

/NOMMS_DEPENDENCIES (D)

Instructs the compiler to produce a dependency file. The format of the dependency file is as follows:

```
object_file_name:<tab><source file name>
object_file_name:<tab><full path to first include file>
object_file_name:<tab><full path to second include file>
```

You can specify none, one, or both of the following qualifier options:

FILE[=filespec]

Specifies where to save the dependency file. The default file extension for a dependency file is `.mms`. Other than using a different default extension, this qualifier uses the same procedure that `/OBJECT` and `/LIST` use for determining the name of the output file.

SYSTEM_INCLUDE_FILES

Specifies whether to include dependency information about system include files (that is, those included with `#include <filename>`). The default is to include dependency information about system include files.

Compiler Command Qualifiers

/MODEL *(Alpha only)*

/MODEL={ANSI | ARM}

/MODEL=ARM (D)

On Alpha systems, determines the layout of C++ classes, name mangling, and exception handling.

On I64 systems, the default (and only) object model & demangling scheme used is the I64 Application Binary Interface (ABI). The compiler accepts the /MODEL qualifier, but it has no effect.

On Alpha systems, /MODEL=ARM is the default and generates objects that are link compatible with all releases prior to HP C++ version 6.3, and with all objects compiled with the /MODEL=ARM qualifier in releases of HP C++ Version 6.3 or later. Specifying this option defines the macro `__MODEL_ARM`.

The /MODEL=ANSI qualifier supports the complete ISO/ANSI C++ specification, including distinct name mangling for templates. The ANSI model also reduces the size of C++ non-POD class objects. Note that this option generates objects that are not compatible with all prior and future releases of HP C++, or with objects compiled using the /MODEL=ARM qualifier.

If you specify the /MODEL=ANSI qualifier, you must recompile and relink (using `CXXLINK/MODEL=ANSI`) your entire application, including libraries. Specifying this option defines the macro `__MODEL_ANSI`.

/NAMES

/NAMES=(option1,option2)

/NAMES=(UPPERCASE,TRUNCATED) (D)

Option1 converts all definitions and references of external symbols and psects to the case specified. Option1 values are:

Option	Usage
UPPERCASE	Converts to uppercase.
AS_IS	Leaves the case as specified in the source.

Option2 controls whether or not external names greater than 31 characters get truncated or shortened. Option2 values are:

Option	Usage
/NAMES=TRUNCATED (default)	Truncates long external names to the first 31 characters.

Compiler Command Qualifiers

Option	Usage
<code>/NAMES=SHORTENED</code>	Shortens long external names. A shortened name consists of the first 23 characters of the name followed by a 7-character Cyclic Redundancy Check (CRC) computed by looking at the full name, and then a "\$".

The default is `/NAMES=(UPPERCASE,TRUNCATED)`.

Note

The I64 C++ compiler has some additional encoding rules that are applied to symbol names after the ABI name mangling is determined. All symbols with C++ linkage have CRC encodings added to the name, are uppercased and shorten to 31 characters if necessary. Since the CRC is computed before the name is uppercased, the symbol name is case-sensitive even though the final name is in uppercase. `/NAMES=AS_IS` and `/NAMES=UPPER` are not applicable to these symbols.

All symbols without C++ linkage will have CRC encodings added if they are longer than 31 characters and `/NAMES=SHORTEN` is specified. Global variables with C++ linkage are treated as if they have non-C++ linkage for compatibility with C and older compilers.

`/NESTED_INCLUDE_DIRECTORY` `/NESTED_INCLUDE_DIRECTORY[=option]` `/NESTED_INCLUDE_DIRECTORY=INCLUDE_FILE (D)`

Controls the first step in the search algorithm the compiler uses when looking for files included using the quoted form of the `#include` preprocessing directive: `#include "file-spec"` The `/NESTED_INCLUDE_DIRECTORY` qualifier has the following options:

Option	Usage
<code>PRIMARY_FILE</code>	Directs the compiler to search the default file type for headers using the context of the primary source file. This means that only the file type (".H" or ".") is used for the default file-spec but, in addition, the chain of "related file-specs" used to maintain the sticky defaults for processing the next top-level source file is applied when searching for the include file.

Compiler Command Qualifiers

Option	Usage
INCLUDE_FILE	Directs the compiler to search the directory containing the file in which the #include directive itself occurred. The meaning of "directory containing" is: the RMS "resultant string" obtained when the file in which the #include occurred was opened, except that the filename and subsequent components are replaced by the default file type for headers (".H", or just "." if /ASSUME=NOHEADER_TYPE_DEFAULT is in effect). The "resultant string" will not have translated any concealed device logical.
NONE	Directs the compiler to skip the first step of processing #include "file.h" directives. The compiler starts its search for the include file in the /INCLUDE_DIRECTORY directories.

For more information on the search order for included files, see the /INCLUDE_DIRECTORY qualifier.

/OBJECT

/OBJECT[=file-spec]

/OBJECT=.OBJ (D)

/NOOBJECT

Controls whether the compiler produces an output object module. The default output file extension is .OBJ.

Note that the /OBJECT qualifier has no impact on the output file of the /MMS_DEPENDENCIES qualifier.

/OPTIMIZE

/OPTIMIZE[=option]

/OPTIMIZE=(LEVEL=4,INLINE=AUTOMATIC,INTRINSICS,UNROLL=0,NOOVERRIDE_LIMITS,TUNE=GENERIC) (D)

/NOOPTIMIZE

Controls the level of code optimization that the compiler performs. The options are as follows:

Option	Usage
LEVEL= <i>n</i>	Selects the level of code optimization. Specify an integer from 0 (no optimization) to 5 (full optimization).

Compiler Command Qualifiers

Option	Usage
[NO]INLINE	Provides inline expansion of functions that yield optimized code when they are expanded. You can specify one of the following keywords to control inlining:
NONE	No inlining is done, even if requested by the language syntax.
MANUAL	Inlines only those function calls for which the program explicitly requests inlining.
AUTOMATIC	Inlines all of the function calls in the MANUAL category, plus additional calls that the compiler determines are appropriate on this platform. On Alpha systems, the heuristics for AUTOMATIC are similar to those for SIZE; on I64 systems, they are more like those for SPEED. AUTOMATIC is the default.
SIZE	Inlines all of the function calls in the MANUAL category plus any additional calls that the compiler determines would improve run-time performance without significantly increasing the size of the program.
SPEED	Performs more aggressive inlining for run-time performance, even when it might significantly increase the size of the program.
ALL	Inlines every call that can be inlined while still generating correct code. Recursive routines, however, will not cause an infinite loop at compile time. On I64 systems, ALL is treated as if SIZE had been specified. Note that /OPT=INLINE=ALL is not recommended for general use, because it performs very aggressive inlining and can cause the compiler to exhaust virtual memory or take an unacceptably long time to compile.

Compiler Command Qualifiers

Option	Usage
[NO]OVERRIDE_ LIMITS <i>(164 only)</i>	<p data-bbox="431 646 1227 779">Controls whether or not the compiler uses certain built-in limits on the size and complexity of a function to "throttle back" the amount of optimization performed in order to reduce the likelihood that the compiler will use excessive memory resources or CPU time attempting to optimize the code.</p> <p data-bbox="431 789 1177 947">The default is NOOVERRIDE_LIMITS, which means that when compiling a function that has an unusually large number of basic blocks, live variables, or other properties that tend to cause the optimizer to use extra resources, the informational message OPTLIMEXC might be issued to notify you that optimization has been reduced to avoid excessive resource use.</p> <p data-bbox="431 957 1227 1014">You can choose to ignore this message or disable it (the message is not issued on compilations with optimization disabled).</p> <p data-bbox="431 1024 1242 1129">Or you can specify /OPTIMIZE=OVERRIDE_LIMITS, which instructs the compiler to not check the limits and to attempt full optimization no matter how large or complex the function, knowing that the compilation might exhaust memory or seem to be in a loop.</p> <p data-bbox="431 1140 1222 1350">If using /OPTIMIZE=OVERRIDE_LIMITS does result in excessive resource use, you are sure that the compiler process has plenty of memory quota available, you are convinced that the compilation does not contain any unusually large or complex functions, and you can provide complete source code, then you might want to contact your support channel to see if there is a problem in the compiler causing it to use more resources than it should for the particular compilation at hand.</p>

Compiler Command Qualifiers

Option	Usage												
TUNE	<p>Specifies the preferred processor for execution. This option makes some decisions preferentially for the specified processor (for example, for code scheduling). Note that code valid only for the specified processor can be generated. However, parallel code can be generated for processors down to the specified architecture level if necessary; that is, tuning specifies the preferred target, while architecture level specifies a lower boundary on available processor features.</p> <p>For example, <code>/ARCHITECTURE=EV56/OPTIMIZE=TUNE=EV6</code> specifies that the code does not need to run on a processor older than an EV56, and that the code will probably run on an EV6. The generated code will run on all EV56 and later systems without any emulation. The code might have run-time selected conditional regions specifically for EV6. Also, note that because emulation is provided, the code should run, but potentially at very significantly reduced speed, on pre-EV56 processors.</p> <p>The options for TUNE are the same as the options for <code>/ARCH</code>. You can specify one of the following keywords:</p> <table><tbody><tr><td>GENERIC</td><td>Selects instruction tuning that is appropriate for all implementations of the operating system architecture. This option is the default.</td></tr><tr><td>HOST</td><td>Selects instruction tuning that is appropriate for the machine on which the code is being compiled.</td></tr><tr><td>ITANIUM2 <i>(I64 only)</i></td><td>Selects instruction tuning for the Intel Itanium 2 processor.</td></tr><tr><td>EV4 <i>(Alpha only)</i></td><td>Selects instruction tuning for the 21064, 21064A, 21066, and 21068 implementations of the operating system architecture.</td></tr><tr><td>EV5 <i>(Alpha only)</i></td><td>Selects instruction tuning for the 21164 implementation of the operating system architecture.</td></tr><tr><td>EV56 <i>(Alpha only)</i></td><td>Selects instruction tuning for 21164 chip implementations that use the byte- and word-manipulation instruction extensions of the Alpha architecture.</td></tr></tbody></table> <p>Running programs compiled with the EV56 keyword might incur emulation overhead on EV4 and EV5 processors, but will still run correctly on OpenVMS Version 7.1 (or later) systems.</p>	GENERIC	Selects instruction tuning that is appropriate for all implementations of the operating system architecture. This option is the default.	HOST	Selects instruction tuning that is appropriate for the machine on which the code is being compiled.	ITANIUM2 <i>(I64 only)</i>	Selects instruction tuning for the Intel Itanium 2 processor.	EV4 <i>(Alpha only)</i>	Selects instruction tuning for the 21064, 21064A, 21066, and 21068 implementations of the operating system architecture.	EV5 <i>(Alpha only)</i>	Selects instruction tuning for the 21164 implementation of the operating system architecture.	EV56 <i>(Alpha only)</i>	Selects instruction tuning for 21164 chip implementations that use the byte- and word-manipulation instruction extensions of the Alpha architecture.
GENERIC	Selects instruction tuning that is appropriate for all implementations of the operating system architecture. This option is the default.												
HOST	Selects instruction tuning that is appropriate for the machine on which the code is being compiled.												
ITANIUM2 <i>(I64 only)</i>	Selects instruction tuning for the Intel Itanium 2 processor.												
EV4 <i>(Alpha only)</i>	Selects instruction tuning for the 21064, 21064A, 21066, and 21068 implementations of the operating system architecture.												
EV5 <i>(Alpha only)</i>	Selects instruction tuning for the 21164 implementation of the operating system architecture.												
EV56 <i>(Alpha only)</i>	Selects instruction tuning for 21164 chip implementations that use the byte- and word-manipulation instruction extensions of the Alpha architecture.												

Compiler Command Qualifiers

Option	Usage
	<p>PCA56 (<i>Alpha only</i>) Selects instruction tuning for the 21164PC chip implementation that uses the byte- and word-manipulation instruction extensions and multimedia instruction extensions of the Alpha architecture.</p> <p>Programs compiled with the PCA56 keyword might incur emulation overhead on EV4, EV5, and EV56 processors, but will still run correctly on OpenVMS Version 7.1 (or later) systems.</p>
	<p>EV6 (<i>Alpha only</i>) Selects instruction tuning for the first-generation 21264 implementation of the Alpha architecture.</p>
	<p>EV67 (<i>Alpha only</i>) Selects instruction tuning for the second-generation 21264 implementation of the Alpha architecture.</p>
[NO]INTRINSICS	<p>Controls whether certain functions are handled as intrinsic functions without explicitly enabling each of them as an intrinsic through the <code>#pragma intrinsic</code> preprocessor directive.</p> <p>Functions that can be handled as intrinsics are:</p> <p>Main Group - ANSI:</p> <pre>abs atanl atan2l ceil cosl floorf memcpy sinf atan atan ceil cos fabs floorl memmove sinl sin atanf atan2f ceilf cosf floor labs memset strcpy strlen</pre> <p>Main Group - Non-ANSI:</p> <pre>alloca atand2 bzero sind atand bcopy cosd</pre> <p>Printf functions:</p> <pre>fprintf printf sprintf</pre> <p>Printf non-ANSI:</p> <pre>snprintf</pre>

Compiler Command Qualifiers

Option	Usage
	ANSI math functions that set errno, thereby requiring /ASSUME=NOMATH_ERRNO:
	acos asinf coshl log log10f powl sqrt tanf acosf asinl exp logf log10l sinh sqrtf tanl acosl cosh expf logl pow sinhf sqrtl tanh tanhl asin coshf expl log10 powf sinhl tan tanhf
	Non-ANSI math functions that set errno, thereby requiring /ASSUME=NOMATH_ERRNO:
	log2 tand
	The /OPTIMIZE=INTRINSICS qualifier works with /OPTIMIZE=LEVEL= <i>n</i> and some other qualifiers to determine how intrinsics are handled:
	<ul style="list-style-type: none">• If the optimization level specified is less than 4, the intrinsic-function prototypes and call formats are checked, but normal run-time calls are still made.• If the optimization level is 4 or higher, intrinsic code is generated.• Intrinsic code is not generated for math functions that set the errno variable unless /ASSUME=NOMATH_ERRNO is specified. Such math functions, however, do have their prototypes and call formats checked.
	The default is /OPTIMIZE=INTRINSICS, which turns on this handling.
	To turn it off, use /NOOPTIMIZE or /OPTIMIZE=NOINTRINSICS.
UNROLL= <i>n</i>	Controls loop unrolling done by the optimizer. Specify a positive integer to indicate the number of times to unroll loop bodies. If you specify 0 or do not supply a value, the optimizer determines its own unroll amount. The default is UNROLL=0. Specifying UNROLL=1 effectively disables loop unrolling.
	On I64 systems, you do not have the ability to control the number of times a loop is unrolled. You can either disable loop unrolling with UNROLL=1, or accept the UNROLL=0 default, which lets the optimizer determine the unroll amount.

The default is /OPTIMIZE, which is equivalent to /OPTIMIZE=LEVEL=4.

Compiler Command Qualifiers

/PENDING_INSTANTIATIONS
/PENDING_INSTANTIATIONS[=n]
/PENDING_INSTANTIATIONS=64(D)

Limit the depth of recursive instantiations so that infinite instantiation loops can be detected before some resource is exhausted. The `/PENDING_INSTANTIATIONS` qualifier requires a positive non-zero value as argument and issues an error when `n` instantiations are pending for the same class template. The default value for `n` is 64.

/POINTER_SIZE
/POINTER_SIZE=option
/NOPOINTER_SIZE (D)

Controls whether pointer-size features are enabled, and whether pointers are 32 bits or 64 bits long.

On both Alpha and I64 systems, the default is `/NOPOINTER_SIZE`, which disables pointer-size features, such as the ability to use `#pragma pointer_size`, and directs the compiler to assume that all pointers are 32-bit pointers. This default represents no change over previous versions of HP C++.

You can specify one of the following options:

SHORT The compiler assumes 32-bit pointers.
32 Same as SHORT.
LONG The compiler assumes 64-bit pointers.
64 Same as LONG.

Specifying `/POINTER_SIZE=32` directs the compiler to assume that all pointers are 32-bit pointers. But unlike the default of `/NOPOINTER_SIZE`, `/POINTER_SIZE=32` enables use of the `#pragma pointer_size long` and `#pragma pointer_size short` preprocessor directives to control pointer size throughout your program.

Specifying `/POINTER_SIZE=64` directs the compiler to assume that all pointers are 64-bit pointers, and also enables use of the `#pragma pointer_size` directives.

/PREFIX_LIBRARY_ENTRIES
/PREFIX_LIBRARY_ENTRIES=(option,...)
/NOPREFIX_LIBRARY_ENTRIES
/PREFIX_LIBRARY_ENTRIES=ALL_ENTRIES (D)

Controls C Run-Time Library (RTL) name prefixing. For user programs that do not include the ANSI header files but call the ANSI library, the compiler automatically adds a `DECC$` prefix to all C RTL library calls just before the name for the external reference or global definition is put into

Compiler Command Qualifiers

the object file. The C RTL shareable image (DECC\$SHR.EXE) resides in IMAGELIB.OLB with a DECC\$ prefix for its entry points. Every external name in IMAGELIB.OLB has a DECC\$ prefix, and, therefore, has an OpenVMS-conformant name space (a requirement for inclusion in IMAGELIB).

The options are as follows:

Option	Usage
EXCEPT=(<i>name</i> , . . .)	The names specified are not prefixed.
ALL_ENTRIES	All HP C++ names are prefixed. Note: ALL_ENTRIES prefixes all functions defined by the C99 standard, including those that may not be supported in the current run-time library. So calling functions introduced in C99 that are not yet implemented in the OpenVMS C RTL will produce unresolved references to symbols prefixed by DECC\$ when the program is linked. In addition, the compiler will issue a CC-W-NOTINCRCTL message when it prefixes a name that is not in the current C RTL.
ANSI_C89_ENTRIES	Only ANSI/ISO C library names are prefixed.
RTL= <i>name</i>	References to the C RTL, indicated by NAME, are generated. NAME must be 1017 characters or fewer.

If you want no names prefixed, specify /NOPREFIX_LIBRARY_ENTRIES.

/PREPROCESS_ONLY
/PREPROCESS_ONLY[=*filename*]
/NOPREPROCESS_ONLY (D)

Causes the compiler to perform only the actions of the preprocessor phase and write the resulting processed text out to a file. The default output file extension is .IXX. Use of /PREPROCESS_ONLY prevents the generation of an object or XREF file.

/PSECT_MODEL
/PSECT_MODEL=MULTILANGUAGE
/PSECT_MODEL=NOMULTILANGUAGE (D)

Controls whether the compiler allocates the size of overlaid psects to ensure compatibility when the psect is shared by code created by other HP compilers.

This qualifier solves a problem that can occur when a psect generated by a Fortran COMMON block is overlaid with a psect consisting of a C struct. Because Fortran COMMON blocks are not padded, if the C struct is padded, the inconsistent psect sizes can cause linker error messages.

Compiler Command Qualifiers

Compiling with `/PSECT_MODEL=MULTILANGUAGE` ensures that the compiler uses a consistent psect size allocation scheme. The corresponding Fortran squalifier is `/ALIGN=COMMON=[NO]MULTILANGUAGE`.

The default is `/PSECT=NOMULTILANGUAGE`, which should be sufficient for most applications.

/PURE_CNAME

/PURE_CNAME (D) (/STANDARD=STRICT_ANSI)

/NOPURE_CNAME (D) (All other modes)

Affects insertion of the names into the global namespace by `<cname>` headers.

In `/PURE_CNAME` mode, the `<cname>` headers insert the names into the `std` namespace only, as defined by the C++ Standard. In this mode, the `__PURE_CNAME` and `__HIDE_FORBIDDEN_NAMES` macros are predefined by the compiler.

In `/NOPURE_CNAME` mode, the `<cname>` headers insert the name into the `std` namespace and also into the global namespace. In this mode, the `__PURE_CNAME` and `__HIDE_FORBIDDEN_NAMES` macros are not predefined by the compiler.

The default depends on the standard mode:

- In `/STANDARD=STRICT_ANSI` mode, the default is `/PURE_CNAME`.
- In all other standard modes, the default is `/NOPURE_CNAME`.

Inclusion of a `<name>` header instead of its `<cname>` counterpart (for example, `<stdio.h>` instead of `<cstdio>`) results in inserting names defined in the header into both the `std` namespace and the global namespace. Effectively, this is the same as the inclusion of a `<cname>` header in `/NOPURE_CNAME` mode.

/QUIET

/QUIET

/NOQUIET (D)

Specifying `/QUIET` causes the compiler to report errors like the Version 5.n compiler (issue fewer messages). This is the default for ARM mode (`/STANDARD=ARM`). All other modes default to `/NOQUIET`.

Use `/WARNINGS=ENABLE` to enable specific messages normally disabled with `/QUIET`.

Compiler Command Qualifiers

/REENTRANCY

/REENTRANCY=option

/REENTRANCY=TOLERANT (D)

Controls the type of reentrancy that reentrant HP C RTL routines exhibit. (See also the `DECC$SET_REENTRANCY` RTL routine.)

This qualifier is for use only with a module containing the main routine.

The reentrancy level is set at run time according to the `/REENTRANCY` qualifier specified while compiling the module containing the main routine. This option affects the behavior of the C RTL, but has no effect on the C++ libraries.

You can specify one of the following options:

Option	Usage
AST	Uses the <code>_TESTBITSSI</code> built-in function to perform simple locking around critical sections of RTL code, and may additionally disable asynchronous system traps (ASTs) in locked region of codes. This type of locking should be used when AST code contains calls to DEC C RTL I/O routines.
MULTITHREAD	Designed to be used in conjunction with the DECthreads product. It performs DECthreads locking and never disables ASTs.
NONE	Gives optimal performance in the RTL, but does absolutely no locking around critical sections of RTL code. It should be used only in a single threaded environment when there is no chance that the thread of execution will be interrupted by an AST that would call the HP C RTL.
TOLERANT	Uses the <code>_TESTBITSSI</code> built-in function to perform simple locking around critical sections of RTL code, but ASTs are not disabled. This type of locking should be used when ASTs are used and must be delivered immediately. This is the default reentrancy type.

/REPOSITORY

/REPOSITORY=(PATHNAME [...])

/REPOSITORY=[.CXX_REPOSITORY] (D)

Specifies a repository that C++ uses to store requested template instantiations. The default is `/REPOSITORY=[.CXX_REPOSITORY]`. If multiple repositories are specified, only the first is considered writable and the default repository is ignored unless specified.

Compiler Command Qualifiers

/ROUNDING_MODE

/ROUNDING_MODE=option

/ROUNDING_MODE=NEAREST (D)

Lets you select an IEEE rounding mode if `/FLOAT=IEEE_FLOAT` is specified. The options are as follows:

Option	Usage
CHOPPED	Rounds toward 0.
DYNAMIC	Sets the rounding mode for IEEE floating-point instructions dynamically, as determined from the contents of the floating-point control register.
MINUS_INFINITY	Rounds toward minus infinity.
NEAREST	Sets the normal rounding mode (unbiased round to nearest). This is the default.

If you specify either `/FLOAT=G_FLOAT` or `/FLOAT=D_FLOAT`, then rounding defaults to `/ROUNDING_MODE=NEAREST`, with no other choice of rounding mode.

/RTTI

/RTTI (D)

/NORTTI (*Alpha only*)

Enables or disables support for RTTI (runtime type identification) features: `dynamic_cast` and `typeid`. Disabling runtime type identification can also save space in your object file because static information to describe polymorphic C++ types is not generated. The default is to enable runtime type information features and generate static information in the object file. The `/RTTI` qualifier defines the macro `__RTTI`.

Note that specifying `/NORTTI` does not disable exception handling.

/SHARE_GLOBALS

/SHARE_GLOBALS

/NOSHARE_GLOBALS (D)

Controls whether the initial `extern_model` is shared or not shared (for those `extern_models` where it is allowed). The initial `extern_model` of the compiler is a fictitious pragma constructed from the settings of the `/EXTERN_MODEL` and `/SHARE_GLOBALS`.

Compiler Command Qualifiers

The default value is `/NOSHARE_GLOBALS`, which has the following effects:

- When linking old object files or object libraries with newly produced object files, you might get "conflicting attributes for psect" messages, which can be safely ignored as long as you are not building shareable libraries.
- The `/noshare_globals` default makes building shareable libraries easier.

/SHOW

/SHOW=(option[,...])

/SHOW=(HEADER,SOURCE) (D)

Used with the `/LIST` qualifier to set or cancel specific listing options. You can select the following options:

Option	Usage
ALL	Print all listing information.
[NO]HEADER	Print/do not print header lines at the top of each page (D = HEADER)
[NO]INCLUDE	Print/do not print contents of <code>#include</code> files (D = NOINCLUDE)
NONE	Print no listing information
[NO]SOURCE	Print/do not print source file statements (D = SOURCE)
[NO]STATISTICS	Print/do not print compiler performance statistics (D = NOSTATISTICS). On I64 systems, the <code>/SHOW=STATISTICS</code> option is ignored.

/STANDARD

/STANDARD=(option)

/STANDARD=RELAXED (D)

The compiler implements the International ANSI C++ Standard. The `/STANDARD` qualifier directs the compiler to interpret source code according to certain nonstandard syntax conventions followed by other implementations of the C++ language. The options are:

Compiler Command Qualifiers

Option	Usage
RELAXED	Allow language constructs required by the International ANSI C++ Standard. This mode also supports some non-ANSI extensions and issues messages for some nonstandard usage that does not strictly comply with the standard. This is the default compiler mode. This option also defines the macro <code>__STD_ANSI</code> . Please note that ANSI is accepted as a synonym for RELAXED to be compatible with previous C++ versions.
ARM	Minimize source changes when compiling programs developed using Version 5.n. This option also defines the macro <code>__STD_ARM</code> . The <code>/STANDARD=ARM</code> qualifier uses the pre-ansi AT&T version of the <code>iostream</code> library and defines the macro <code>__NO_USE_STD_IOSTREAM</code> .
CFRONT	As of HP C++ Version 7.1, support for <code>/STANDARD=CFRONT</code> is retired.
GNU	<p>Use this option if you want to compile programs developed using the GNU C++ compiler. This option also defines the <code>__STD_GNU</code> macro. The <code>/STANDARD=GNU</code> qualifier uses the pre-ansi AT&T version of the <code>iostream</code> library and defines the macro <code>__NO_USE_STD_IOSTREAM</code>. The following changes in behavior are provided for compatibility with the GNU C++ compiler:</p> <ul style="list-style-type: none">• These options are enabled by default: <code>/ALTERNATIVE_TOKENS</code> <code>/TEMPLATE_DEFINE=LOCAL</code> <code>/NO_IMPLICIT_INCLUDE</code>• Access control is not enforced for types defined inside a class.• Unrecognized character escape sequences in string literals produce an informational instead of a warning message.• The <code>__INLINE</code> keyword is enabled and is equivalent to <code>inline</code>.• The severity of the error "incompatible parameter" (tag <code>incompatibleprm</code>) is reduced to warning.• When overloading, enum types are treated as integral types. <p>The following known incompatibility is not addressed in the <code>/STANDARD=GNU</code> mode:</p> <ul style="list-style-type: none">• The compiler strictly enforces the requirement to define functions before they are used. This requirement also applies to built-in functions such as <code>strlen</code>.

Compiler Command Qualifiers

Option	Usage
MS	Allow language constructs supported by the Visual C++ compiler. This option also defines the macro <code>__STD_MS</code> . The <code>/STANDARD=MS</code> qualifier uses the pre-ansi AT&T version of the <code>iostream</code> library and defines the macro <code>__NO_USE_STD_Iostream</code> .
STRICT_ANSI	Enforce the ANSI standard strictly but permit some ANSI violations that should be errors to be warnings. This option also defines the macro <code>__STD_STRICT_ANSI</code> . To force ANSI violations to be issued as errors instead of warnings, use <code>/WARNINGS=ANSI_ERRORS</code> in addition to <code>/STANDARD=STRICT_ANSI</code> . This combination defines the macro <code>__STD_STRICT_ANSI_ERRORS</code> . The <code>/STANDARD=STRICT_ANSI</code> qualifier uses the ANSI/ISO standard version of the <code>iostream</code> library and defines the macro <code>__USE_STD_Iostream</code> .
LATEST	Latest C++ standard dialect (<i>Alpha, 164</i>). <code>/STANDARD=LATEST</code> is currently equivalent to <code>/STANDARD=STRICT_ANSI</code> , but is subject to change when newer versions of the C++ standard are released.

For more information on the effect of the `/STANDARD` qualifier on HP C++ compile-time error checking, Section E.1.

`/TEMPLATE_DEFINE=(option,...)`

`/NOTEMPLATE_DEFINE`

Controls compiler behavior pertaining to the instantiation of C++ templates. See Chapter 5 for details on how to instantiate templates using this qualifier. Note that you must specify a value for this qualifier.

`/UNDEFINE`

`/UNDEFINE=(identifier[,...])`

`/NOUNDEFINE (D)`

Performs the same function as the `#undef` preprocessor directive: it cancels a macro definition.

The `/UNDEFINE` qualifier is useful for undefining the predefined C++ preprocessor constants. For example, if you use a preprocessor constant to conditionally compile segments of code specific to C++ for OpenVMS systems, you can undefine constants to see how the portable sections of your program execute. For example:

```
/UNDEFINE="deccxx"
```

When both `/DEFINE` and `/UNDEFINE` are present on the CXX command line, `/DEFINE` is evaluated before `/UNDEFINE`.

Compiler Command Qualifiers

/UNSIGNED_CHAR

/UNSIGNED_CHAR

/NOUNSIGNED_CHAR (D)

The `/UNSIGNED_CHAR` qualifier changes the default for all char types from signed to unsigned. The `/NOUNSIGNED_CHAR` qualifier causes all plain char declarations to have the same representation and set of values as signed char declarations.

/USING_STD

/USING_STD

/NOUSING_STD (D)

Controls whether standard library header files are processed as though the compiled code were written as follows:

```
using namespace std;
#include <header>
```

These options are provided for compatibility for users who do not want to qualify use of each standard library name with `std::` or `using namespace std;` at the top of their sources.

`/USING_STD` turns implicit using namespace `std` on; this is the default when compiling `/STANDARD=ARM`, `/STANDARD=GNU`, `/STANDARD=MS`, or `/STANDARD=RELAXED`.

`/NOUSING_STD` turns implicit using namespace `std` off; this is the default when compiling `/STANDARD=STRICT_ANSI`.

/VERSION

/VERSION

/NOVERSION (D)

Causes the compiler to identify (print out) its version and operating system. The listing file also contains the compiler version. You cannot specify this qualifier with any other qualifiers.

/WARNINGS

/WARNINGS[=(option[,...])]

/WARNINGS (D)

/NOWARNINGS

Controls the issuance of compiler diagnostic messages and lets you modify the severity of messages.

The default qualifier, `/WARNINGS`, outputs all enabled warning and informational messages for the compiler mode you are using. The `/NOWARNINGS` qualifier suppresses warning and informational messages.

Options apply only to warning and informational messages.

Compiler Command Qualifiers

The *message-list* in the following table of options can be any one of the following:

- A single message identifier (within parentheses, or not). The message identifier is the name following the message severity letter on the first line of an issued message. For example, in the following message, the message identifier is GLOBALEXT:

```
%CC-W-GLOBALEXT, a storage class of globaldef, globalref, or globalvalue  
is a language extension.
```

- A comma-separated list of message identifiers, enclosed in parentheses.
- The keyword ALL.

The options are processed and take effect in the following order:

Compiler Command Qualifiers

NOWARNINGS	Suppresses warnings.
NOINFORMATIONALS	Suppresses informational messages.
ENABLE= <i>message-list</i>	Enables issuance of the specified messages. Can be used to enable specific messages that normally would not be issued when using /QUIET or messages disabled with /WARNINGS=DISABLE.
DISABLE= <i>message-list</i>	Disables issuance of the specified messages. Can be used for any nonerror message specified by a message number or tag. Specify ALL to suppress all informationals and warnings.
INFORMATIONALS= <i>message-list</i>	Sets the severity of all specified messages to Informational. Fatal and Error messages cannot be made less severe. Can also be used to enable informationals that are disabled by default. Note: With C++ Version 7.1, using /WARNINGS=INFORMATIONALS=<tag> no longer enables all other informational messages.
WARNINGS= <i>message-list</i>	Sets the severity of the specified messages to Warning. Fatal and Error messages cannot be made less severe.
[NO]ANSI_ERRORS	Issues error messages for all ANSI violations when in STRICT_ANSI mode. The default is /WARNINGS=NOANSI_ERRORS.
[NO]TAGS	Displays a descriptive tag at the end of each message. "D" indicates that the severity of the message can be controlled from the command line. The tag displayed can be used as the message identifier in the /WARNINGS qualifier options.
ERRORS= <i>message-list</i>	Sets the severity of the specified messages to Error. Supplied Error and Fatal messages cannot be made less severe. (Exception: A message can be upgraded from Error to Fatal, then later downgraded to Error again, but it can never be downgraded from Error.) Warnings and Informationals can be made any severity.
FATALS= <i>message-list</i>	Sets the severity of the specified messages to Fatal.

Also see the #pragma message preprocessor directive.

Compiler Command Qualifiers

/XREF *(Alpha only)*

/XREF[=file-spec]

/NOXREF (D)

Controls whether the compiler generates a file of source code analysis information. The default file name is the file name of the primary source file; the default file type is .XREF. Use the SCA IMPORT command to convert an .XREF file into an analysis data file that is ready for loading into an SCA library.

B

Programming Tools

This appendix provides information on tools that you can use to develop and refine your C++ programs. Some ship with the OpenVMS operating system but others require separate purchase.

B.1 DEC Language-Sensitive Editor

The DEC Language-Sensitive Editor (LSE) is a text editor intended specifically for software development. LSE includes the following features:

- Formatted language constructs, or templates, for most DEC programming languages. These templates include keywords and required punctuation, and use placeholders to indicate where to insert optional or required code.
- Commands for compiling, reviewing, and correcting compilation errors from within the editor.
- Integration with DEC Code Management System (CMS). You can enter CMS commands from within the editor to coordinate the progress of program development on OpenVMS systems. For more information on CMS, see the *Guide to DEC Code Management System*.

B.1.1 Starting and Terminating an LSE Session

To invoke LSE and associate a buffer with C++, use the following syntax:

```
LSEEDIT [qualifier...]filename.cxx
```

To invoke LSE without associating the editing buffer with a programming language, enter the following command at the DCL prompt:

```
$ lseedit file-spec
```

To end an LSE session, press Ctrl/Z to get the LSE> prompt. Then, enter the exit command if you want to save the current file modification, or enter the quit command if you want to discard the current file modification.

Programming Tools

B.1 DEC Language-Sensitive Editor

B.1.2 LSE Placeholders and Tokens

The language-sensitive features of LSE simplify the tasks of writing and maintaining program code. Among these features are placeholders and tokens.

Placeholders are markers in the source code that indicate where a program element is expected. Placeholders are worded to denote the appropriate syntax in a given context. You do not need to type placeholders; LSE inserts them, surrounded by brackets ([]) or braces ({} and at signs (@). Braces indicate where source code is required in the program's context; brackets indicate that you have the option of supplying additional constructs or erasing the placeholder.

Tokens are LSE words that, when expanded, provide additional language constructs. You can type tokens directly into the buffer. You use tokens in situations such as modifying an existing program to add program elements where no placeholders exist. For example, if you type `while` and then enter the `expand` command, a template for a `while` construct appears in your buffer in place of the characters you typed. You also can use tokens as a shortcut in situations where expanding a placeholder would entail a complicated sequence of actions.

LSE has commands for manipulating tokens and placeholders, as follows:

Command	Default Key Binding	Description
<code>expand</code>	Ctrl/E	Expands a placeholder
<code>unexpand</code>	PF1-Ctrl/E	Reverses the effect of the most recent placeholder expansion
<code>goto placeholder/forward</code>	Ctrl/N	Moves the cursor forward to the next placeholder
<code>goto placeholder/reverse</code>	Ctrl/P	Moves the cursor backward to the previous placeholder
<code>erase placeholder/forward</code>	Ctrl/K	Erases a placeholder
<code>unerase placeholder</code>	PF1-Ctrl/K	Restores the most recently erased placeholder

Programming Tools

B.1 DEC Language-Sensitive Editor

Command	Default Key Binding	Description
↓	Down arrow	Moves the selection indicator downward through a screen menu
↑	up arrow	Moves the selection indicator upward through a screen menu
{ Enter } { Return }	<input type="text" value="Enter"/> <input type="text" value="Return"/>	Selects a menu option

To display a list of all the predefined tokens supplied with C++, enter the following LSE command:

```
LSE> show token
```

To display a list of all the predefined placeholders supplied with C++, enter the following LSE command:

```
LSE> show placeholder
```

For information about a particular token or placeholder, specify the name of the token or placeholder after the `show token` or `show placeholder` command.

To create a list of either tokens or placeholders, first execute the appropriate `show` command to put the list in the `$show` buffer. Then, enter the following commands:

```
LSE> go buffer $show
LSE> write file-spec
```

When you exit LSE, you can use the DCL `print` command to print a copy of the file you wrote.

B.1.3 Compiling and Reviewing Source Code from an LSE Session

To compile your source code and to review compilation errors without leaving the editing session, use the LSE commands `compile` and `review`. The `compile` command issues a DCL command in a subprocess to invoke the compiler. The compiler then generates a file of compile-time diagnostic information that LSE uses to review any compilation errors. The diagnostic information is generated with the `/DIAGNOSTICS` qualifier that LSE appends to the compilation command.

Programming Tools

B.1 DEC Language-Sensitive Editor

For example, if you enter the `compile` command while editing the buffer `user.cxx`, LSE executes the following DCL command:

```
$ CXX user.cxx/DIAGNOSTICS=USER.DIA
```

LSE supports all the command qualifiers available with the compiler.

The `/DIAGNOSTICS` qualifier is ignored on I64 systems.

The `review` command displays any diagnostic messages that result from a compilation. LSE displays the compilation errors in one window and corresponding source code in a second window. This lets you view the error messages while examining the associated code.

B.1.4 DEC Source Code Analyzer (SCA)

Although the compiler does not support the DEC Source Code Analyzer (SCA) through the `CXX /ANALYSIS_DATA` command-line qualifier, users can generate a `.ana` file that contains information on all the tokens within a C++ program. For example, users can do the following:

```
SCA> find some_variable_name
```

To use the SCA `analyze` command with C++ files so that in turn you can execute `find` commands on your C++ code from LSE or SCA, do the following:

- At the command line, issue the SCA command:

```
$ SCA
```

- Set your SCA library with the `set library` command. For example:

```
SCA> set library projdisk:[user.any_existing_sca_lib]
```

- Issue the `analyze` command on your `.cxx` file:

```
SCA> analyze testprog.cxx
```

This command places the file `testprog.ana` in your current working directory.

- Load the resulting `.ana` file:

```
SCA> load testprog.ana
```

C

Built-In Functions

This appendix describes the built-in functions available when you compile on OpenVMS systems. These functions allow you to access hardware and machine instructions directly.

These functions allow you to directly access hardware and machine instructions to perform operations that are cumbersome, slow, or impossible in other C++ compilers.

These functions are very efficient because they are built into the HP C++ compiler. This means that a call to one of these functions does not result in a reference to a function in the HP C Run-Time Library or to a function in your program. Instead, the compiler generates the machine instructions necessary to carry out the function directly at the call site. Because most of these built-in functions closely correspond to single Alpha or Itanium machine instructions, the result is small, fast code.

Be sure to include the `<builtins.h>` header file in your source program to access these built-in functions. Definitions for return types `int64` and `uint64` are contained in the header file `<ints.h>`.

Some of the built-in functions have optional arguments or allow a particular argument to have one of many different types. To describe all valid combinations of arguments, the following built-in function descriptions list several different prototypes for the function. As long as a call to a built-in function matches one of the prototypes listed, the call is valid. Furthermore, any valid call to a built-in function behaves as if the corresponding prototype were in scope of the call. The compiler, therefore, performs the argument checking and conversions specified by that prototype.

The majority of the built-in functions are named after the processor instruction that they generate. The built-in functions provide direct and unencumbered access to those processor instructions. Any inherent limitations to those instructions are limitations to the built-in functions as well. For instance, the `MOVC3` instruction and the `_MOVC3` built-in function can move at most 65,535 characters.

Built-In Functions

For more information on the Alpha built-in functions, see the corresponding machine instructions in the *Alpha Architecture Handbook* or *Alpha Architecture Reference Manual*.

For more information on the I64 built-in functions, see the corresponding machine instructions in the *Intel® Itanium® Architecture Software Developer's Manual*.

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

The following sections describe the HP C++ built-in functions available on OpenVMS Alpha systems.

C.1.1 Translation Macros

HP C++ for OpenVMS Alpha systems does not support the built-in functions available with HP C++ for OpenVMS VAX systems. However, the `<builtins.h>` header file contains macro definitions that translate some VAX C built-in functions to the equivalent HP C++ for OpenVMS Alpha built-in functions. Consequently, the following VAX C built-in functions are effectively supported:

```
_BBCCI(position, address)
_BBSSI(position, address)
_INSQHI(new_entry, head)
_INSQTI(new_entry, head)
_INSQUE(new_entry, predecessor)
_REMQHI(head, removed_entry)
_REMQTI(head, removed_entry)
_REMQUE(entry, removed_entry)
_PROBER(mode, length, address)
_PROBEW(mode, length, address)
```

For more detail on any of these functions, see `<builtins.h>` or the description of the corresponding native Alpha function in this chapter. For example, for a description of `_INSQHI`, see `__PAL_INSQHIL`.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

C.1.2 Intrinsic Functions

HP C++ on Alpha systems supports in-line assembly code, commonly called ASMs on UNIX platforms.

Like built-in functions, ASMs are implemented with a function-call syntax. But unlike built-in functions, to use ASMs you must include the `<c_asm.h>` header file containing prototypes for the three types of ASMs, and the `#pragma intrinsic` preprocessor directive.

Syntax:

```
__int64 asm(const char *, ...); /* for integer operations,
                                like mulq */
float fasm(const char *, ...); /* for single precision float
                                instructions */
double dasm(const char *, ...); /* for double precision float
                                instructions */

#pragma intrinsic (asm)
#pragma intrinsic (fasm)
#pragma intrinsic (dasm)
```

The first argument to the `asm`, `fasm`, or `dasm` function contains the instruction(s) to be generated inline and the metalanguage that describes the interpretation of the arguments.

The remaining arguments (if any) are the source and destination arguments for the instruction being generated.

C.1.3 Privileged Architecture Library Code Instructions

The following Privileged Architecture Library Code (PALcode) instructions are available as built-in functions:

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

<code>__PAL_GENTRAP</code>	<code>__PAL_INSQHIL</code>	<code>__PAL_REMQHIL</code>	<code>__PAL_MTPR_ASTEN</code>	<code>__PAL_MFPR_ASTEN</code>

<code>__PAL_WR_PS_SW</code>			<code>__PAL_MTPR_USP</code>	
<code>__PAL_IMB</code>			<code>__PAL_MTPR_VPTB</code>	

The following sections describe these PALcodes.

`__PAL_BPT`

This function is provided for program debugging. It generates a Breakpoint trap.

This function has the following format:

```
void __PAL_BPT (void);
```

`__PAL_BUGCHK`

This function is provided for error reporting. It generates a Bug-check trap.

This function has the following format:

```
void __PAL_BUGCHK (unsigned __int64 code);
```

`__PAL_CFLUSH`

This function flushes at least the entire physical page specified by the page frame number *value* from any data caches associated with the current processor. After a CFLUSH is done, the first subsequent load on the same processor to an arbitrary address in the target page is fetched from physical memory.

This function has the following format:

```
void __PAL_CFLUSH (int value);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

value

A page frame number.

__PAL_CHME

This function allows a process to change its mode to Executive in a controlled manner. The change in mode also results in a change of stack pointers: the old pointer is saved and the new pointer is loaded. Registers R2 to R7, PS, and PC are pushed onto the selected stack. The saved PC addresses the instruction following the CHME instruction.

This function has the following format:

```
void __PAL_CHME (void);
```

__PAL_CHMK

This function allows a process to change its mode to kernel in a controlled manner. The change in mode also results in a change of stack pointers: the old pointer is saved and the new pointer is loaded. Registers R2 to R7, PS, and PC are pushed onto the kernel stack. The saved PC addresses the instruction following the CHMK instruction.

This function has the following format:

```
void __PAL_CHMK (void);
```

__PAL_CHMS

This function allows a process to change its mode to Supervisor in a controlled manner. The change in mode also results in a change of stack pointers: the old pointer is saved and the new pointer is loaded. Registers R2 to R7, PS, and PC are pushed onto the selected stack. The saved PC addresses the instruction following the CHMS instruction.

This function has the following format:

```
void __PAL_CHMS (void);
```

__PAL_CHMU

This function allows a process to call a routine using the change mode mechanism. Registers R2 to R7, PS, and PC are pushed onto the current stack. The saved PC addresses the instruction following the CHMU instruction.

This function has the following format:

```
void __PAL_CHMU (void);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

__PAL_DRAIN

This function stalls instruction issuing until all prior instructions are guaranteed to complete without incurring aborts.

This function has the following format:

```
void __PAL_DRAIN (void);
```

__PAL_GENTRAP

This function is used for reporting run-time software conditions. It generates a Software trap.

This function has the following format:

```
void __PAL_GENTRAP (unsigned __int64 encoded_software_trap);
```

encoded_software_trap

The particular software condition that has occurred.

__PAL_HALT

This function halts the processor when executed by a process running in kernel mode. This is a privileged function.

This function has the following format:

```
void __PAL_HALT (void);
```

__PAL_IMB

This function makes the instruction stream coherent with the data stream. It must be executed after software or I/O devices write into the instruction stream or modify the instruction stream virtual address mapping, and before the new value is fetched as an instruction. Note that executing an IMB on one processor in a multiprocessor environment does not affect instruction caches on other processors.

This function has the following format:

```
void __PAL_IMB (void);
```

__PAL_INSQHIL

This function inserts an entry at the front of a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to header and queue entries. The pointers to *head* and *new_entry* must not be equal.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

This function has the following format:

```
int __PAL_INSQHIL (void *head, void *new_entry);  
/* At head, interlocked */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on a longword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

__PAL_INSQHILR

This function inserts an entry into the front of a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. The pointers to *head* and *new_entry* must not be equal. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_INSQHILR (void *head, void *new_entry);  
/* At head, interlocked resident */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on a quadword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

__PAL_INSQHIQ

This function inserts an entry at the front of a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to header and queue entries. The pointers to *head* and *new_entry* must not be equal.

This function has the following format:

```
int __PAL_INSQHIQ (void *head, void *new_entry);  
/* At head, interlocked */
```

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on an octaword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

__PAL_INSQHIQR

This function inserts an entry into the front of a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. The pointers to *head* and *new_entry* must not be equal. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_INSQHIQR (void *head, void *new_entry);  
/* At head, interlocked resident */
```

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on an octaword boundary.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

__PAL_INSQTIL

This function inserts an entry at the end of a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to header and queue entries. The pointers to *head* and *new_entry* must not be equal.

This function has the following format:

```
int __PAL_INSQTIL (void *head, void *new_entry);  
/* At tail, interlocked */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on a quadword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

__PAL_INSQTILR

This function inserts an entry at the end of a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. The pointers to *head* and *new_entry* must not be equal. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_INSQTILR (void *head, void *new_entry);  
/* At tail, interlocked resident */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on a quadword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

__PAL_INSQTIQ

This function inserts an entry at the end of a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to header and queue entries. The pointers to *head* and *new_entry* must not be equal.

This function has the following format:

```
int __PAL_INSQTIQ (void *head, void *new_entry);  
/* At tail, interlocked */
```

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on an octaword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

__PAL_INSQTIQR

This function inserts an entry at the end of a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. The pointers to *head* and *new_entry* must not be equal. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_INSQTIQR (void *head, void *new_entry);  
/* At tail, interlocked resident */
```

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

new_entry

A pointer to the new entry to be inserted. The entry must be aligned on an octaword boundary.

There are three possible return values:

- -1 if the entry was not inserted because the secondary interlock failed
- 0 if the entry was inserted but it was not the only entry in the list
- 1 if the entry was inserted and it was the only entry in the list

__PAL_INSQUEL

This function inserts a new entry after an existing entry into a longword queue. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_INSQUEL (void *predecessor, void *new_entry);
```

predecessor

A pointer to an existing entry in the queue.

new_entry

A pointer to the new entry to be inserted.

There are two possible return values:

- 0 if the entry was not the only entry in the queue
- 1 if the entry was the only entry in the queue

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

__PAL_INSQUEL_D

This function inserts a new entry after an existing entry into a longword queue deferred. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_INSQUEL_D (void **predecessor, void *new_entry);  
/* Deferred */
```

predecessor

A pointer to a pointer to the predecessor entry.

new_entry

A pointer to the new entry to be inserted.

There are two possible return values:

- 0 if the entry was not the only entry in the queue
- 1 if the entry was the only entry in the queue

__PAL_INSQUEQ

This function inserts a new entry after an existing entry into a quadword queue. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_INSQUEQ (void *predecessor, void *new_entry);
```

predecessor

A pointer to an existing entry in the queue.

new_entry

A pointer to the new entry to be inserted.

There are two possible return values:

- 0 if the entry was not the only entry in the queue
- 1 if the entry was the only entry in the queue

__PAL_INSQUEQ_D

This function inserts a new entry after an existing entry into a quadword queue deferred. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_INSQUEQ_D (void **predecessor, void *new_entry);  
/* Deferred */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

predecessor

A pointer to a pointer to the predecessor entry.

new_entry

A pointer to the new entry to be inserted.

There are two possible return values:

- 0 if the entry was not the only entry in the queue
- 1 if the entry was the only entry in the queue

__PAL_LDQP

This function returns the quadword-aligned memory object specified by *address*.

This function has the following format:

```
unsigned __int64 __PAL_LDQP (void *address);
```

address

A pointer to the quadword-aligned memory object to be returned.

If the object pointed to by *address* is not quadword-aligned, the result is unpredictable.

__PAL_MFPR_XXXX

These privileged functions return the contents of a particular processor register. The *XXXX* indicates the processor register to be read.

These functions have the following format:

```
/* AST Enable */
unsigned int __PAL_MFPR_ASTEN (void);
/* AST Summary Register */
unsigned int __PAL_MFPR_ASTSR (void);
/* Executive Stack Pointer */
void *__PAL_MFPR_ESP (void);
/* Floating-Point Enable */
int __PAL_MFPR_FEN (void);
/* Interrupt Priority Level */
int __PAL_MFPR_IPL (void);
/* Machine Check Error Summary */
int __PAL_MFPR_MCES (void);
/* Privileged Context Block Base */
void *__PAL_MFPR_PCBB (void);
/* Processor Base Register */
__int64 __PAL_MFPR_PRBR (void);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

```
/* Page Table Base Register */
int __PAL_MFPR_PTBR (void);
/* System Control Block Base */
void *__PAL_MFPR_SCBB (void);
/* Software Interrupt Summary Register */
unsigned int __PAL_MFPR_SISR (void);
/* Supervisor Stack Pointer */
void *__PAL_MFPR_SSP (void);
/* Translation Buffer Check */
__int64 __PAL_MFPR_TBCHK (void *address);
/* User Stack Pointer */
void *__PAL_MFPR_USP (void);
/* Virtual Page Table */
void *__PAL_MFPR_VPTB (void);
/* Who Am I */ __int64 __PAL_MFPR_WHAMI (void);
```

__PAL_MTPR_XXXX

These privileged functions load a value into one of the special processor registers. The *XXXX* indicates the processor register to be loaded.

These functions have the following format:

```
/* AST Enable */
void __PAL_MTPR_ASTEN (unsigned int mask);
/* AST Summary Register */
void __PAL_MTPR_ASTR (unsigned int mask);
/* Data Alignment Trap Fixup */
void __PAL_MTPR_DATFX (int value);
/* Executive Stack Pointer */
void __PAL_MTPR_ESP (void *address);
/* Floating-Point Enable */
void __PAL_MTPR_FEN (int value);
/* Interprocessor Interrupt Request */
void __PAL_MTPR_IPIR (__int64 number);
/* Interrupt Priority Level */
int __PAL_MTPR_IPL (int value);
/* Machine Check Error Summary */
void __PAL_MTPR_MCES (int value);
/* Processor Base Register */
void __PAL_MTPR_PRBR (__int64 value);
/* System Control Block Base */
void __PAL_MTPR_SCBB (void *address);
/* Software Interrupt Request Register */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

```
void __PAL_MTPR_SIRR (int level);  
/* Supervisor Stack Pointer */  
void __PAL_MTPR_SSP (int *address);  
/* Translation Buffer Invalidate All*/  
void __PAL_MTPR_TBIA (void);  
/* Translation Buffer Invalidate All Process */  
void __PAL_MTPR_TBIAP (void);  
/* Translation Buffer Invalidate Single */  
void __PAL_MTPR_TBIS (void *address);  
/* Translation Buffer Invalidate Single Data */  
void __PAL_MTPR_TBISD (void *address);  
/* Translation Buffer Invalidate Single Instruction */  
void __PAL_MTPR_TBISI (void *address);  
/* User Stack Pointer */  
void __PAL_MTPR_USP (void *address);  
/* Virtual Page Table */ void __PAL_MTPR_VPTB (void *address);
```

__PAL_PROBER

This function checks the write accessibility of the first and last byte of the given address and length pair.

This function has the following format:

```
int __PAL_PROBER (const void *base_address, int length,  
char mode);
```

base_address

The pointer to the memory segment to be tested for read access.

length

The length of the memory segment, in bytes.

mode

The processor mode used for checking access.

There are two possible return values:

- 0 if both bytes are not accessible
- 1 if both bytes are accessible

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

__PAL_PROBEW

This function checks the write accessibility of the first and last byte of the given address and length pair.

This function has the following format:

```
int __PAL_PROBEW (const void *base_address, int length,
char mode);
```

base_address

The pointer to the memory segment to be tested for write access.

length

The length of the memory segment, in bytes.

mode

The processor mode used for checking access.

There are two possible return values:

- 0 if both bytes are not accessible
- 1 if both bytes are accessible

__PAL_RD_PS

This function returns the Processor Status (PS).

This function has the following format:

```
unsigned __int64 __PAL_RD_PS (void);
```

__PAL_REMQHIL

This function removes the first entry from a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries.

This function has the following format:

```
int __PAL_REMQHIL (void *head, void **removed_entry);
/* At head, interlocked */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQHILR

This function removes the first entry from a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_REMQHILR (void *head, void **removed_entry);  
/* At head, interlocked resident */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQHIQ

This function removes the first entry from a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries.

This function has the following format:

```
int __PAL_REMQHIQ (void *head, void **removed_entry);  
/* At head, interlocked */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQHIQR

This function removes the first entry from a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_REMQHIQR (void *head, void **removed_entry);  
/* At head, interlocked resident */
```

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

__PAL_REMQTIL

This function removes the last entry from a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries.

This function has the following format:

```
int __PAL_REMQTIL (void *head, void **removed_entry);  
/* At tail, interlocked */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQTILR

This function removes the last entry from a longword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_REMQTILR (void *head, void **removed_entry);  
/* At tail, interlocked resident */
```

head

A pointer to the queue header. The header must be aligned on a quadword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQTIQ

This function removes the last entry from a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries.

This function has the following format:

```
int __PAL_REMQTIQ (void *head, void **removed_entry);  
/* At tail, interlocked */
```

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQTIQR

This function removes the last entry from a quadword queue in an indivisible manner. This operation is interlocked against similar operations by other preprocessors or devices in the system. This function must have write access to the header and queue entries. All parts of the queue must be memory resident.

This function has the following format:

```
int __PAL_REMQTIQR (void *head, void **removed_entry);  
/* At tail, interlocked resident */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

head

A pointer to the queue header. The header must be aligned on an octaword boundary.

removed_entry

A pointer to the address of the entry removed from the queue.

There are four possible return values:

- -1 if the entry cannot be removed because the secondary interlock failed
- 0 if the queue was empty
- 1 if the entry was removed and the queue has remaining entries
- 2 if the entry was removed and the queue is now empty

__PAL_REMQUEL

This function removes an entry from a longword queue. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_REMQUEL (void *entry, void **removed_entry);
```

entry

A pointer to the queue entry to be removed.

removed_entry

A pointer to the address of the entry removed from the queue.

There are three possible return values:

- -1 if the queue was empty
- 0 if the entry was removed and the queue is now empty
- 1 if the entry was removed and the queue has remaining entries

__PAL_REMQUEL_D

This function removes an entry from a longword queue deferred. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_REMQUEL_D (void **entry, void **removed_entry);  
/* Deferred */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

entry

A pointer to a pointer to the queue entry to be removed.

removed_entry

A pointer to the address of the entry removed from the queue.

There are three possible return values:

- -1 if the queue was empty
- 0 if the entry was removed and the queue is now empty
- 1 if the entry was removed and the queue has remaining entries

__PAL_REMQUEQ

This function removes an entry from a quadword queue. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_REMQUEQ (void *entry, void **removed_entry);
```

entry

A pointer to the queue entry to be removed.

removed_entry

A pointer to the address of the entry removed from the queue.

There are three possible return values:

- -1 if the queue was empty
- 0 if the entry was removed and the queue is now empty
- 1 if the entry was removed and the queue has remaining entries

__PAL_REMQUEQ_D

This function removes an entry from a quadword queue deferred. This function must have write access to header and queue entries.

This function has the following format:

```
int __PAL_REMQUEQ_D (void **entry, void **removed_entry);  
/* Deferred */
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

entry

A pointer to a pointer to the queue entry to be removed.

removed_entry

A pointer to the address of the entry removed from the queue.

There are three possible return values:

- -1 if the queue was empty
- 0 if the entry was removed and the queue is now empty
- 1 if the entry was removed and the queue has remaining entries

__PAL_STQP

This function writes the quadword *value* to the memory location pointed to by *address*.

This function has the following format:

```
void __PAL_STQP (void *address, unsigned __int64 value);
```

address

Memory location to be written to.

value

Quadword value to be stored.

If the location pointed to by *address* is not quadword-aligned, the result is unpredictable.

__PAL_SWASTEN

This function swaps the previous state of the Asynchronous System Trap (AST) enable bit for the new state. The new state is supplied in bit 0 of *new_state_mask*. The previous state is returned, zero-extended.

A check is made to determine if an AST is pending. If the enabling conditions are present for an AST at the completion of this instruction, the AST occurs before the next instruction.

This function has the following format:

```
unsigned int __PAL_SWASTEN (int new_state_mask);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

new_state_mask

An integer whose 0 bit is the new state of the AST enable bit.

__PAL_SWPCTX

This function returns ownership of the data structure that contains the current hardware privileged context (the HWPCB) to the operating system and passes ownership of the new HWPCB to the processor.

This function has the following format:

```
void __PAL_SWPCTX (void *address);
```

address

A pointer to the new HWPCB.

__PAL_WR_PS_SW

This function writes the low-order three bits of *mask* into the Processor Status software field (PS<SW>).

This function has the following format:

```
void __PAL_WR_PS_SW (int mask);
```

mask

An integer whose low-order three bits are written into PS<SW>.

C.1.4 Other Builtins

Absolute Value (__ABS)

The `__ABS` built-in is functionally equivalent to its counterpart, `abs`, in the standard header file `<stdlib.h>`.

Its format is also the same:

```
#include <stdlib.h>
int __ABS (int x);
```

This built-in function does, however, offer performance improvements because there is less call overhead associated with its use.

If you include `<stdlib.h>`, the built-in function is automatically used for all occurrences of `abs`. To disable the built-in function, use `#undef abs`.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Acquire and Release Longword Semaphore (`__ACQUIRE_SEM_LONG`, `__RELEASE_SEM_LONG`)

The `__ACQUIRE_SEM_LONG` and `__RELEASE_SEM_LONG` functions provide a counted semaphore capability where the positive value of a longword is interpreted as the number of resources available.

The `__ACQUIRE_SEM_LONG` function loops until the longword has a positive value and then decrements it within a load-locked/store-conditional sequence; it then issues a memory barrier. This function returns 1 if the resource count was successfully decremented within the specified number of retries, and 0 otherwise. With no explicit retry count, the function does not return until it succeeds.

The `__RELEASE_SEM_LONG` function issues a memory barrier and then does an `__ATOMIC_INCREMENT_LONG` on the longword.

The `__ACQUIRE_SEM_LONG` function has the following formats:

```
int __ACQUIRE_SEM_LONG (volatile void *address);
int __ACQUIRE_SEM_LONG_RETRY (volatile void *address, int retry);
```

The `__RELEASE_SEM_LONG` function has the following format:

```
int __RELEASE_SEM_LONG (volatile void *address);
```

address

The longword-aligned address of the resource count.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

Add Aligned Word Interlocked (`__ADAWI`)

The `__ADAWI` function adds its source operand to the destination. This function is interlocked against similar operations by other processors or devices in the system.

This function has the following format:

```
int __ADAWI (short src, short *dest);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

src

The value to be added to the destination.

dest

A pointer to the destination. The destination must be aligned on a word boundary.

The `__ADAWI` function returns a simulated VAX processor status longword (PSL).

Add Atomic Longword (`__ADD_ATOMIC_LONG`)

The `__ADD_ATOMIC_LONG` function adds the specified expression to the longword data segment pointed to by the address parameter within a load-locked/store-conditional code sequence.

This function has the following format:

```
int __ADD_ATOMIC_LONG int fnc(void *, int, ...);
```

address

The address of the data segment.

expression

An integer expression.

...

An optional retry count of type `int`. If specified, the retry count indicates the number of times the operation is attempted. If the operation cannot be performed successfully in the specified number of retries, a value of 0 is returned.

A value of 1 is returned upon successful completion.

Add Atomic Quadword (`__ADD_ATOMIC_QUAD`)

The `__ADD_ATOMIC_QUAD` function adds the specified expression to the quadword data segment pointed to by the address parameter within a load-locked/store-conditional code sequence.

This function has the following format:

```
int __ADD_ATOMIC_QUAD (void *address, int expression, ...);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

address

The address of the data segment.

expression

An integer expression.

...

An optional retry count of type `int`. If specified, the retry count indicates the number of times the operation is attempted. If the operation cannot be performed successfully in the specified number of retries, a value of 0 is returned.

A value of 1 is returned upon successful completion.

AND Atomic Longword (`__AND_ATOMIC_LONG`)

The `__AND_ATOMIC_LONG` function performs a bit-wise or arithmetic AND of the specified expression with the aligned longword pointed to by the address parameter within a load-locked/store-conditional code sequence.

This function has the following format:

```
int __AND_ATOMIC_LONG (void *address, int expression, ...);
```

address

The longword-aligned address of the data segment.

expression

An integer expression.

...

An optional retry count of type `int`. If specified, the retry count indicates the number of times the operation is attempted (which will be at least once, even if the count argument is 0). If the operation cannot be performed successfully in the specified number of retries, a value of 0 is returned.

A value of 1 is returned upon successful completion.

AND Atomic Quadword (`__AND_ATOMIC_QUAD`)

The `__AND_ATOMIC_QUAD` function performs a bit-wise or arithmetic AND of the specified expression with the aligned quadword pointed to by the address parameter within a load-locked/store-conditional code sequence.

This function has the following format:

```
int __AND_ATOMIC_QUAD (void *address, int expression, ...);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

address

The address of the aligned quadword.

expression

An integer expression.

...

An optional retry count of type `int`. If specified, the retry count indicates the number of times the operation is attempted (which will be at least once, even if the count argument is 0). If the operation cannot be performed successfully in the specified number of retries, a value of 0 is returned.

A value of 1 is returned upon successful completion.

Atomic Add Longword (`__ATOMIC_ADD_LONG`)

The `__ATOMIC_ADD_LONG` function adds the specified expression to the aligned longword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the longword before the addition was performed.

This function has one of the following formats:

```
int __ATOMIC_ADD_LONG (volatile void *address,  
int expression);
```

```
int __ATOMIC_ADD_LONG_RETRY (volatile void *address,  
int expression, int retry,  
int *status);
```

address

The longword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Atomic Add Quadword (`__ATOMIC_ADD_QUAD`)

The `__ATOMIC_ADD_QUAD` function adds the specified expression to the aligned quadword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the quadword before the addition was performed.

This function has one of the following formats:

```
int __ATOMIC_ADD_QUAD (volatile void *address,  
int expression);
```

```
int __ATOMIC_ADD_QUAD_RETRY (volatile void *address,  
int expression, int retry,  
int *status);
```

address

The quadword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic AND Longword (`__ATOMIC_AND_LONG`)

The `__ATOMIC_AND_LONG` function performs a bit-wise or arithmetic AND of the specified expression with the aligned longword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the longword before the operation was performed.

This function has one of the following formats:

```
int __ATOMIC_AND_LONG (volatile void *address,  
int expression);
```

```
int __ATOMIC_AND_LONG_RETRY (volatile void *address,  
int expression, int retry,  
int *status);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

address

The longword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic AND Quadword (`__ATOMIC_AND_QUAD`)

The `__ATOMIC_AND_QUAD` function performs a bit-wise or arithmetic AND of the specified expression with the aligned quadword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the quadword before the operation was performed.

This function has one of the following formats:

```
int __ATOMIC_AND_QUAD (volatile void *address,  
int expression);
```

```
int __ATOMIC_AND_QUAD_RETRY (volatile void *address,  
int expression, int retry,  
int *status);
```

address

The quadword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic OR Longword (`__ATOMIC_OR_LONG`)

The `__ATOMIC_OR_LONG` function performs a bit-wise or arithmetic OR of the specified expression with the aligned longword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the longword before the operation was performed.

This function has one of the following formats:

```
int __ATOMIC_OR_LONG (volatile void *address, int expression);
```

```
int __ATOMIC_OR_LONG_RETRY (volatile void *address,  
int expression, int retry, int *status);
```

address

The longword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic OR Quadword (`__ATOMIC_OR_QUAD`)

The `__ATOMIC_OR_QUAD` function performs a bit-wise or arithmetic OR of the specified expression with the aligned quadword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the quadword before the operation was performed.

This function has one of the following formats:

```
int __ATOMIC_OR_QUAD (volatile void *address, int expression);
```

```
int __ATOMIC_OR_QUAD_RETRY (volatile void *address,  
int expression, int retry, int *status);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

address

The quadword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic Increment Longword (`__ATOMIC_INCREMENT_LONG`)

The `__ATOMIC_INCREMENT_LONG` function increments by 1 the aligned longword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the longword before the operation was performed.

This function has the following formats:

```
int __ATOMIC_INCREMENT_LONG (volatile void *address);
```

```
int __ATOMIC_INCREMENT_LONG_RETRY (volatile void *address, int retry, int *status);
```

address

The longword-aligned address of the data segment.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Atomic Increment Quadword (`__ATOMIC_INCREMENT_QUAD`)

The `__ATOMIC_INCREMENT_QUAD` function increments by 1 the aligned quadword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the quadword before the operation was performed.

This function has the following formats:

```
int __ATOMIC_INCREMENT_QUAD (volatile void *address);
```

```
__int64 __ATOMIC_INCREMENT_QUAD (volatile void *address, int retry, int *status);
```

address

The quadword-aligned address of the data segment.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic Decrement Longword (`__ATOMIC_DECREMENT_LONG`)

The `__ATOMIC_DECREMENT_LONG` function decrements by 1 the aligned longword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the longword before the operation was performed.

This function has the following formats:

```
int __ATOMIC_DECREMENT_LONG (volatile void *address);
```

```
int __ATOMIC_DECREMENT_LONG_RETRY (volatile void *address, int retry, int *status);
```

address

The longword-aligned address of the data segment.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic Decrement Quadword (`__ATOMIC_DECREMENT_QUAD`)

The `__ATOMIC_DECREMENT_QUAD` function decrements by 1 the aligned quadword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the quadword before the operation was performed.

This function has the following formats:

```
int __ATOMIC_DECREMENT_QUAD (volatile void *address);
```

```
__int64 __ATOMIC_DECREMENT_QUAD_RETRY (volatile void *address, int retry, int *status);
```

address

The quadword-aligned address of the data segment.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic Exchange Longword (`__ATOMIC_EXCH_LONG`)

The `__ATOMIC_EXCH_LONG` function stores the value of the specified expression into the aligned longword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the longword before the operation was performed.

This function has one of the following formats:

```
int __ATOMIC_EXCH_LONG (volatile void *address,  
int expression);
```

```
int __ATOMIC_EXCH_LONG_RETRY (volatile void *address,  
int expression, int retry, int *status);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

address

The longword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Atomic Exchange Quadword (`__ATOMIC_EXCH_QUAD`)

The `__ATOMIC_EXCH_QUAD` function stores the value of the specified expression into the aligned quadword pointed to by the *address* parameter within a load-locked/store-conditional code sequence and returns the value of the quadword before the operation was performed.

This function has one of the following formats:

```
int __ATOMIC_EXCH_QUAD (volatile void *address,  
int expression);
```

```
int __ATOMIC_EXCH_QUAD_RETRY (volatile void *address, int expression, int retry,  
int *status);
```

address

The quadword-aligned address of the data segment.

expression

An integer expression.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Allocate Bytes from Stack (`__ALLOCA`)

The `__ALLOCA` function allocates n bytes from the stack.

This function has the following format:

```
void * __ALLOCA (unsigned int n);
```

n

The number of bytes to be allocated.

A pointer to the allocated memory is returned.

Single-Precision, Floating-Point Arithmetic Built-in Functions

The following built-in functions provide single-precision, floating-point chopped arithmetic:

```
__ADDF_C    __ADDS_C    __SUBF_C    __SUBS_C  
__MULF_C    __MULS_C    __DIVF_C    __DIVS_C
```

They have the following format:

```
float __op{F,S}_C (float operand1, float operand2);
```

Where *op* is one of ADD, SUB, MUL, DIV, and {F,S} represents VAX or IEEE floating-point arithmetic.

The result of the arithmetic operation is returned.

Double-Precision, Floating-Point Arithmetic Built-in Functions

The following built-in functions provide double-precision, floating-point chopped arithmetic:

```
__ADDG_C    __ADDT_C    __SUBG_C    __SUBT_C  
__MULG_C    __MULT_C    __DIVG_C    __DIVT_C
```

They have the following format:

```
double __op{G,T}_C (double operand1, double operand2);
```

Where *op* is one of ADD, SUB, MUL, DIV, and {G,T} represents VAX or IEEE floating-point arithmetic.

The result of the arithmetic operation is returned.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Copy Sign Built-in Functions

Built-in functions are provided to copy selected portions of single- and double-precision, floating-point numbers.

These built-in functions have the following format:

```
float  __CPYSF (float operand1, float operand2);  
double __CPYS (double operand1, double operand2);
```

```
float  __CPYSNF (float operand1, float operand2);  
double __CPYSN (double operand1, double operand2);
```

```
float  __CPYSEF (float operand1, float operand2);  
double __CPYSE (double operand1, double operand2);
```

The copy sign built-in functions (`__CPYSF` and `__CPYS`) fetch the sign bit in *operand1*, concatenate it with the exponent and fraction bits from *operand2*, and return the result.

The copy sign negate built-in functions (`__CPYSNF` and `__CPYSN`) fetch the sign bit in *operand1*, complement it, concatenate it with the exponent and fraction bits from *operand2*, and return the result.

The copy sign exponent built-in functions (`__CPYSEF` and `__CPYSE`) fetch the sign and exponent bits from *operand1*, concatenate them with the fraction bits from *operand2*, and return the result.

Compare Store Longword (`__CMP_STORE_LONG`)

The `__CMP_STORE_LONG` function has the following format:

```
int  __CMP_STORE_LONG (void *source, int old_value, int new_value, void *dest);
```

This function compares the value pointed to by *source* with the longword *old_value*. If they are equal, the longword *new_value* is stored into the value pointed to by *dest*. The comparison is within a load-locked/store-conditional code sequence.

The function returns 0 if the two values are unequal, if *source* and *dest* are not in the same 16-byte lock region, or if some other process accessed the 16-byte lock region before *new_value* could be stored. The function returns 1 if the two values are equal and *new_value* was stored atomically.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Compare Store Quadword (`__CMP_STORE_QUAD`)

The `__CMP_STORE_QUAD` function has the following format:

```
int __CMP_STORE_QUAD (void *source, __int64 old_value,  
__int64 new_value, void *dest);
```

This function compares the value pointed to by *source* with the quadword *old_value*. If they are equal, the quadword *new_value* is stored into the value pointed to by *dest*. The comparison is within a load-locked/store-conditional code sequence.

The function returns 0 if the two values are unequal, if *source* and *dest* are not in the same 16-byte lock region, or if some other process accessed the 16-byte lock region before *new_value* could be stored. The function returns 1 if the two values are equal and *new_value* was stored atomically.

Cosine (`__COS`)

The `__COS` built-in function is functionally equivalent to its counterpart, `cos`, in the standard header file `<math.h>`.

Its format is also the same:

```
#include <math.h>  
double __COS (double x);
```

x

A radian value.

This built-in function does, however, offer performance improvements because there is less call overhead associated with its use.

If you include `<math.h>`, the built-in function is automatically used for all occurrences of `cos`. To disable the built-in function, use `#undef cos`.

Convert G_Floating to F_Floating Chopped (`__CVTGF_C`)

The `__CVTGF_C` function converts a double-precision, VAX G_floating-point number to a single-precision, VAX F_floating-point number. This conversion chops to single-precision; then the 8-bit exponent range is checked for overflow or underflow.

This function has the following format:

```
float __CVTGF_C (double operand);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

operand

A double-precision, VAX floating-point number.

Convert G-Floating to Quadword (__CVTGQ)

The __CVTGQ function rounds a double-precision, VAX floating-point number to a 64-bit integer value and returns the result.

This function has the following format:

```
__int64 __CVTGQ (double operand);
```

operand

A double-precision, VAX floating-point number.

Convert IEEE T_Floating to IEEE S_Floating Chopped (__CVTTS_C)

The __CVTTS_C function converts a double-precision, IEEE T_floating-point number to a single-precision, IEEE S_floating-point number. This conversion chops to single-precision; then the 8-bit exponent range is checked for overflow or underflow.

This function has the following format:

```
float __CVTTS_C (double operand);
```

operand

A double-precision, IEEE floating-point number.

Convert IEEE T-Floating to Quadword (__CVTTQ)

The __CVTTQ function rounds a double-precision, IEEE-floating-point number to a 64-bit integer value and returns the result.

This function has the following format:

```
__int64 __CVTTQ (double operand);
```

operand

A double-precision, IEEE T-floating-point number.

Floating-Point Absolute Value (__FABS)

The __FABS built-in function is functionally equivalent to its counterpart, fabs, in the standard header file <math.h>.

Its format is also the same:

```
#include <math.h>  
double __FABS (double x);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

x

A floating-point number.

This built-in function does, however, offer performance improvements because there is no call overhead associated with its use.

If you include `<math.h>`, the built-in function is automatically used for all occurrences of `fab`. To disable the built-in function, use `#undef fab`.

Test for Bit Clear then Clear Bit Interlocked (`__INTERLOCKED_TESTBITCC_QUAD`)

The `__INTERLOCKED_TESTBITCC_QUAD` function performs the following functions in interlocked fashion:

1. Returns the complement of the specified bit before being cleared.
2. Clears the bit.

This function has the following formats:

```
int __INTERLOCKED_TESTBITCC_QUAD (volatile void *address, int bit_position);
```

```
int __INTERLOCKED_TESTBITCC_QUAD_RETRY (volatile void *address, int bit_position, int retry,  
int *status);
```

address

The quadword-aligned base address of the bit field.

bit_position

The position within the field of the bit that you want cleared, in the range of 0 to 63.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the `retry` argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the quadword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Test for Bit Set Then Set Bit Interlocked (`__INTERLOCKED_TESTBITSS_QUAD`)

The `__INTERLOCKED_TESTBITSS_QUAD` function performs the following functions in interlocked fashion:

1. Returns the value of the specified bit before being set.
2. Sets the bit.

This function has the following formats:

```
int __INTERLOCKED_TESTBITSS_QUAD (volatile void *address, int bit_position);
```

```
int __INTERLOCKED_TESTBITSS_QUAD_RETRY (volatile void *address, int expression, int retry,  
int *status);
```

address

The quadword-aligned base address of the bit field.

bit_position

The position within the field of the bit that you want cleared, in the range of 0 to 63.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

status

A pointer to an integer that is set to 0 if the operation did not succeed within the specified number of retries, and set to 1 if the operation succeeded.

_leadz

The `_leadz` built-in function returns the number of leading zeroes (starting at the most significant bit position) in its argument. For example, `_leadz(1)` returns 63, and `_leadz(0)` returns 64.

This function has the following format:

```
__int64 _leadz (unsigned __int64);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Lock and Unlock Longword (`__LOCK_LONG`, `__UNLOCK_LONG`)

The `__LOCK_LONG` and `__UNLOCK_LONG` functions provide a binary spinlock capability based on the low-order bit of a longword.

The `__LOCK_LONG` function executes in a loop waiting for the bit to be cleared and then sets it within a load-locked/store-conditional sequence; it then issues a memory barrier. The `__UNLOCK_LONG` function issues a memory barrier and then zeroes the longword.

The `__LOCK_LONG_RETRY` function returns 1 if the lock was acquired in the specified number of retries and 0 if the lock was not acquired.

The `__LOCK_LONG` function has the following formats:

```
int __LOCK_LONG (volatile void *address);
```

```
int __LOCK_LONG_RETRY (volatile void *address, int retry);
```

The `__UNLOCK_LONG` function has the following format:

```
int __UNLOCK_LONG (volatile void *address);
```

address

The quadword-aligned address of the longword used for the lock.

retry

A retry count of type `int` that indicates the number of times the operation is attempted (which is at least once, even if the *retry* argument is 0). If the operation cannot be performed successfully in the specified number of retries, the function returns without updating the longword.

Longword Absolute Value (`__LABS`)

The `__LABS` built-in function is functionally equivalent to its counterpart, `labs`, in the standard header file `<stdlib.h>`.

Its format is also the same:

```
#include <stdlib.h>
long int __LABS (long int x);
```

x

An integer.

This built-in function does, however, offer performance improvements because there is less call overhead associated with its use.

If you include `<stdlib.h>`, the built-in function is automatically used for all occurrences of `labs`. To disable the built-in function, use `#undef labs`.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Memory Barrier (`__MB`)

The `__MB` function directs the compiler to generate a memory barrier instruction.

This function has the following format:

```
void __MB (void);
```

Memory Copy and Set Functions (`__MEMCPY`, `__MEMMOVE`, `__MEMSET`)

The `__MEMCPY`, `__MEMMOVE`, and `__MEMSET` built-in functions are functionally equivalent to their counterparts in the standard header file `<string.h>`.

Their format is also the same:

```
#include <string.h>
void *__MEMCPY (void *s1, const void *s2, size_t size);
void *__MEMMOVE (void *s1, const void *s2, size_t size);
void *__MEMSET (void *s, int value, size_t size);
```

These built-in functions do, however, offer performance improvements because there is less call overhead associated with their use.

If you include `<string.h>`, the built-in functions are automatically used for all occurrences of `memcpy`, `memmove`, and `memset`. To disable the built-in functions, use `#undef memcpy`, `#undef memmove`, and `#undef memset`.

`_popcnt`

The `_popcnt` built-in function returns the number of "1" bits (0 to 64) in its argument. For example, `_popcnt(12)` returns 2.

This function has the following format:

```
__int64 _popcnt (unsigned __int64);
```

`_poppar`

The `_poppar` built-in function returns 1 if the number of "1" bits in its argument is odd; otherwise it returns 0. For example, `_poppar(12)` returns 0.

This function has the following format:

```
__int64 _poppar (unsigned __int64);
```

Read Process Cycle Counter (`__RPCC`)

The `__RPCC` function reads the current process cycle counter.

This function has the following format:

```
__int64 __RPCC (void);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Sine (`__SIN`)

The `__SIN` built-in function is functionally equivalent to its counterpart in the standard header file `<math.h>`.

Its format is also the same:

```
#include <math.h>
double __SIN (double x);
```

x

A radian value.

This built-in function does, however, offer performance improvements because there is less call overhead associated with its use.

If you include `<math.h>`, the built-in function is used automatically for all occurrences of `sin`. To disable the built-in function, use `#undef sin`.

Test for Bit Clear then Clear Bit Interlocked (`__TESTBITCCI`)

The `__TESTBITCCI` function performs the following operations in interlocked fashion:

- Returns the complement of the specified bit before being cleared
- Clears the bit

This function has the following format:

```
int __TESTBITCCI (void *address, int position, ...);
```

address

The base address of the field.

position

The position within the field of the bit that you want cleared.

...

An optional retry count of type `int`. If specified, the retry count indicates the number of times the operation is attempted. If the operation cannot be performed successfully in the specified number of retries, a value of 0 is returned.

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

Test for Bit Set then Set Bit Interlocked (`__TESTBITSSI`)

The `__TESTBITSSI` function performs the following operations in interlocked fashion:

- Returns the value of the specified bit before being set
- Sets the bit

This function has the following format:

```
int __TESTBITSSI (void *address, int position, ...);
```

address

The base address of the field.

position

The position within the field of the bit that you want set.

...

An optional retry count of type `int`. If specified, the retry count indicates the number of times the operation is attempted. If the operation cannot be performed successfully in the specified number of retries, a value of 0 is returned.

`_trailz`

The `_trailz` built-in function returns the number of trailing zeros (counting after the least significant set bit to the least significant bit position) in its argument. For example, `_trailz(2)` returns 1, and `_trailz(0)` returns 64.

This function has the following format:

```
__int64 _trailz (unsigned __int64);
```

Trap Barrier Instruction (`__TRAPB`)

The `__TRAPB` function allows software to guarantee that, in a pipeline implementation, all previous arithmetic instructions will be completed without incurring any arithmetic traps before any instructions after the `TRAPB` instruction are issued.

This function has the following format:

```
void __TRAPB (void);
```

Unsigned Quadword Multiply High (`__UMULH`)

The `__UMULH` function performs a quadword multiply high instruction.

This function has the following format:

```
unsigned __int64 __UMULH (unsigned __int64 operand1, unsigned __int64 operand2);
```

Built-In Functions

C.1 Built-In Functions for Alpha Systems *(Alpha only)*

operand1

A 64-bit unsigned integer.

operand2

A 64-bit unsigned integer.

The two operands are multiplied as unsigned integers to produce a 128-bit result. The high order 64-bits are returned.

C.2 Built-In Functions for I64 Systems *(I64 only)*

The HP C++ built-in functions available on OpenVMS Alpha systems are also available on I64 systems, with some differences, as described in this section. This section also describes built-in functions that are specific to I64 systems.

C.2.1 Builtin Differences on I64 Systems

The `<builtins.h>` header file contains comments noting which built-in functions are not available or are not the preferred form for I64 systems. The compiler issues diagnostics where using a different built-in function for I64 systems would be preferable.

Note

The comments in `<builtins.h>` reflect only what is explicitly present in that header file itself, and in the compiler implementation. You should also consult the content and comments in `<pal_builtins.h>` to determine more accurately what functionality is effectively provided by including `<builtins.h>`. For example, if a program explicitly declares one of the Alpha built-in functions and invokes it without having included `<builtins.h>`, the compiler might issue the BIFNOTAVAIL error message, regardless of whether or not the function is available through a system service. If the compilation does include `<builtins.h>`, and BIFNOTAVAIL is issued, then either there is no support at all for the built-in function or a new version of `<pal_builtins.h>` is needed.

Here is a summary of these differences on I64 systems:

- There is no support for the `asm`, `fasm`, and `dasm` intrinsics (declared in the `<c_asm.h>` header file).

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

- The functionality provided by the special-case treatment of R26 in an Alpha system asm, as in `asm("MOV R26,R0")`, is provided by a new built-in function for I64 systems:

```
__int64 __RETURN_ADDRESS(void);
```

This built-in function produces the address to which the function containing the built-in call will return (the value of R26 on entry to the function on Alpha systems; the value of B0 on entry to the function on I64 systems). This built-in function cannot be used within a function specified to use nonstandard linkage.

- The only PAL function calls implemented as built-in functions within the compiler are the 24 queue-manipulation builtins. The queue manipulation builtins generate calls to new OpenVMS system services SYS\$<name>, where <name> is the name of the builtin with the leading underscores removed.

Any other OpenVMS PAL calls are supported through macros defined in the `<pal_builtins.h>` header file included in the `<builtins.h>` header file. Typically, the macros in `<pal_builtins.h>` transform an invocation of an Alpha system builtin into a call to a system service that performs the equivalent function on an I64 system. Two notable exceptions are `__PAL_GENTRAP` and `__PAL_BUGCHK`, which instead invoke the I64 specific compiler builtin `__break2`.

- There is no support for the various floating-point built-in functions used by the OpenVMS math library (for example, operations with chopped rounding and conversions).
- For most built-in functions that take a retry count, the compiler issues an error message. Such builtins must be replaced with the corresponding builtin that does not have a retry count. This is necessary because the retry behavior allowed by Alpha load-locked/store-conditional sequences does not exist on I64 systems. There are two exceptions to this: `__LOCK_LONG_RETRY` and `__ACQUIRE_SEM_LONG_RETRY`; in these cases, the retry behavior involves comparisons of data values, not just load-locked/store-conditional.
- The `__CMP_STORE_LONG` and `__CMP_STORE_QUAD` built-in functions produce an error message, and must be replaced with the new `__CMP_SWAP_LONG` and `__CMP_SWAP_QUAD` built-in functions.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

C.2.2 Built-in Functions Specific to I64 Systems

The `<builtins.h>` header file contains a section at the top conditionalized to just `__ia64` with the support for built-in functions specific to I64 systems. This includes macro definitions for all of the registers that can be specified to the `__getReg`, `__setReg`, `__getIndReg`, and `__setIndReg` built-in functions. Parameters that are `const`-qualified require an argument that is a compile-time constant.

The following sections describe the HP C++ built-in functions available on OpenVMS I64 systems.

Get Hardware Register Value (`__getReg`)

The `__getReg` function gets the value from a hardware register based on the register index specified. This function produces a corresponding `mov = r` instruction.

This function has the following format:

```
unsigned __int64 __getReg (const int whichReg);
```

whichReg

The index of the hardware register from which the value is obtained. The `__getReg` and `__setReg` functions can access the following registers:

Register Name	<i>whichReg</i>
<code>__IA64_REG_IP</code>	1016
<code>__IA64_REG_PSR</code>	1019
<code>__IA64_REG_PSR_L</code>	1019

General Integer Registers:

Register Name	<i>whichReg</i>
<code>__IA64_REG_GP</code>	1025
<code>__IA64_REG_SP</code>	1036
<code>__IA64_REG_TP</code>	1037

* `getReg` only

Set Hardware Register Value (`__setReg`)

The `__setReg` function sets the value for a hardware register based on the register index specified. This function produces a corresponding `mov = r` instruction.

This function has the following format:

```
void __setReg (const int whichReg, unsigned __int64 value);
```

whichReg

The index of the hardware register whose value is being set. See the `__getReg` functions for the list of registers that can be accessed.

value

The value to which the register is set.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

Get Index Register Value (`__getIndReg`)

The `__getIndReg` function returns the value of an indexed register. The function accesses a register (*index*) in a register file (*whichIndReg*) of 64-bit registers.

This function has the following format:

```
unsigned __int64 __getIndReg (const int whichIndReg, __int64 index);
```

whichIndReg

The register file.

index

The index in the register file of the hardware register whose value is being requested. See the `__getReg` functions for the list of registers that can be accessed.

Indirect Registers for `getIndReg` and `setIndReg`:

Register Name	<i>whichReg</i>
<code>__IA64_REG_INDR_CPUID</code>	9000 *
<code>__IA64_REG_INDR_DBR</code>	9001
<code>__IA64_REG_INDR_IBR</code>	9002
<code>__IA64_REG_INDR_PKR</code>	9003
<code>__IA64_REG_INDR_PMC</code>	9004
<code>__IA64_REG_INDR_PMD</code>	9005
<code>__IA64_REG_INDR_RR</code>	9006
<code>__IA64_REG_INDR_RESERVED</code>	9007

* `getIndReg` only

Set Index Register Value (`__setIndReg`)

The `__setIndReg` function copies a value into an indexed register. The function accesses a register (*index*) in a register file (*whichIndReg*) of 64-bit registers.

This function has the following format:

```
void __setIndReg (const int whichIndReg, __int64 index, unsigned __int64 value);
```

whichIndReg

The register file.

index

The index in the register file of the hardware register to be set. See the `__getIndReg` function for the list of registers that can be accessed.

value

The value to which the register is set.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

Generate Break Instruction (`__break`)

The `__break` function generates a break instruction with an immediate.

This function has the following format:

```
void __break (const int __break_arg);
```

`__break_arg`

An immediate value for the `__break` instruction to use.

Serialize Data (`__dsrlz`)

The `__dsrlz` function serializes data. Maps to the `srlz.d` instruction.

This function has the following format:

```
void __dsrlz (void);
```

Flush Cache Instruction (`__fc`)

The `__fc` function flushes a cache line associated with the address given by the argument. Maps to the `fc` instruction.

This function has the following format:

```
void __fc (__int64 __address);
```

`__address`

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Flush Write Buffers (`__fwb`)

The `__fwb` function flushes the write buffers. Maps to the `fwb` instruction.

This function has the following format:

```
void __fwb (void);
```

Invalidate ALAT (`__invalat`)

The `__invalat` function invalidates ALAT. Maps to the `invala` instruction.

This function has the following format:

```
void __invalat (void);
```

Invalidate ALAT (`__invala`)

The `__invala` function is the same as the `__invalat` function.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

Execute Serialize (`__isrlz`)

The `__isrlz` function executes the serialize instruction. Maps to the `srlz.i` instruction.

This function has the following format:

```
void __isrlz (void);
```

Insert Data Address Translation Cache (`__itcd`)

The `__itcd` function inserts an entry into the data translation cache. Maps to the `itc.d` instruction.

This function has the following format:

```
void __itcd (_int64 pa);
```

pa

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Insert Instruction Address Translation Cache (`__itci`)

The `__itci` function inserts an entry into the instruction translation cache. Maps to the `itc.i` instruction.

This function has the following format:

```
void __itci (_int64 pa);
```

pa

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Insert Data Translation Register (`__itrd`)

The `__itrd` function maps to the `itr.d` instruction.

This function has the following format:

```
void __itrd (_int64 whichTransReg, _int64 pa);
```

whichTransReg

The data translation register to be used by the `itr.d` instruction.

pa

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

Insert Instruction Translation Register (`__itri`)

The `__itri` function maps to the `itr.i` instruction.

This function has the following format:

```
void __itri ( __int64 whichTransReg, __int64 pa );
```

whichTransReg

The data translation register to be used by the `itr.i` instruction.

pa

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Purge Translation Cache Entry (`__ptce`)

The `__ptce` function maps to the `ptc.e` instruction.

This function has the following format:

```
void __ptce ( __int64 va );
```

va

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Purge Global Translation Cache (`__ptcg`)

The `__ptcg` function purges the global translation cache. Maps to the `ptc.g r,r` instruction.

This function has the following format:

```
void __ptcg ( __int64 va, __int64 pagesz );
```

va

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

pagesz

The address range of the purge.

Purge Local Translation Cache (`__ptcl`)

The `__ptcl` function purges the local translation cache. Maps to the `ptc.l r,r` instruction.

This function has the following format:

```
void __ptcl ( __int64 va, __int64 pagesz );
```

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

va

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

pagesz

The address range of the purge.

Purge Global Translation Cache and ALAT (`__ptcga`)

The `__ptcga` function purges the global translation cache and ALAT. Maps to the `ptc.ga r,r` instruction.

This function has the following format:

```
void __ptcga (_int64 va, _int64 pagesz);
```

va

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

pagesz

The address range of the purge.

Purge Data Translation Register (`__ptrd`)

The `__ptrd` function purges the data translation register. Maps to the `ptr.d r,r` instruction.

This function has the following format:

```
void __ptrd (_int64 va, _int64 pagesz);
```

va

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

pagesz

The address range of the purge.

Purge Instruction Translation Register (`__ptri`)

The `__ptri` function purges the instruction translation register. Maps to the `ptr.i r,r` instruction.

This function has the following format:

```
void __ptri (_int64 va, _int64 pagesz);
```

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

va

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

pagesz

The address range of the purge.

Reset System Mask (__rsm)

The __rsm function resets the system mask bits of the PSR. Maps to the rsm imm24 instruction.

This function has the following format:

```
void __rsm (int mask);
```

mask

An integer value inserted into the instruction as a 24-bit immediate value.

Reset User Mask (__rum)

The __rum function resets the user mask.

This function has the following format:

```
void __rum (int mask);
```

mask

An integer value inserted into the instruction as a 24-bit immediate value.

Set System Mask (__ssm)

The __ssm function sets the system mask.

This function has the following format:

```
void __ssm (int mask);
```

mask

An integer value inserted into the instruction as a 24-bit immediate value.

Set User Mask (__sum)

The __sum function sets the user mask bits of the PSR. Maps to the sum imm24 instruction.

This function has the following format:

```
void __sum (int mask);
```

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

mask

An integer value inserted into the instruction as a 24-bit immediate value.

Enable Memory Synchronization (__synci)

The __synci function enables memory synchronization. Maps to the sync.i instruction.

This function has the following format:

```
void __synci(void);
```

Translation Hashed Entry Address (__thash)

The __thash function generates a translation hash entry address. Maps to the thash r = r instruction.

This function has the following format:

```
void __thash(__int64 __address);
```

__address

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Translation Hashed Entry Tag (__ttag)

The __ttag function generates a translation hash entry tag. Maps to the ttag r=r instruction.

This function has the following format:

```
void __ttag(__int64 __address);
```

__address

A 64-bit address, as opposed to a 32-bit or 64-bit pointer, that is loaded into a 64-bit general register used by the instruction to be generated.

Atomic Compare and Exchange (_InterlockedCompareExchange_acq)

The _InterlockedCompareExchange_acq function atomically compares and exchanges the value specified by the first argument (a 64-bit pointer). This function maps to the cmpxchg4.acq instruction with appropriate setup.

This function has the following format:

```
unsigned __int64 _InterlockedCompareExchange_acq (volatile unsigned int *Destination,  
unsigned __int64 Newval, unsigned __int64 Comparand);
```

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

The value at **Destination* is compared with the value specified by *Comparand*. If they are equal, *Newval* is written to **Destination*, and *Oldval* is returned. The exchange will have taken place if the value returned is equal to the *Comparand*. The following algorithm is used:

```
ar.ccv = Comparand;
Oldval = *Destination;           //Atomic
if (ar.ccv == *Destination)     //Atomic
    *Destination = Newval;      //Atomic
return Oldval;
```

Those parts of the algorithm that are marked "Atomic" are performed atomically by the `cmpxchg4.acq` instruction. This instruction has acquire ordering semantics; that is, the memory read/write is made visible prior to all subsequent data memory accesses of the *Destination* by other processors.

Destination

The value to be compared with *Comparand* and, if equal, replaced with the value of *Newval*.

Newval

The new value to replace the value in *Destination*.

Comparand

The value with which to compare *Destination*.

Atomic Compare and Exchange (`_InterlockedCompareExchange64_acq`)

The `_InterlockedCompareExchange64_acq` function is the same as the `_InterlockedCompareExchange_acq` function, except that those parts of the algorithm that are marked "Atomic" are performed by the `cmpxchg8.acq` instruction.

This function has the following format:

```
unsigned __int64  _InterlockedCompareExchange64_acq (volatile unsigned __int64 *Destination,
                                                    unsigned __int64 Newval, unsigned __int64 Comparand);
```

Atomic Compare and Exchange (`_InterlockedCompareExchange_rel`)

This function is the same as the `_InterlockedCompareExchange_acq` function except that those parts of the algorithm that are marked "Atomic" are performed by the `cmpxchg4.rel` instruction with release ordering semantics; that is, the memory read/write is made visible after all previous memory accesses of the *Destination* by other processors.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

This function has the following format:

```
unsigned __int64  _InterlockedCompareExchange_rel (volatile unsigned int *Destination,  
                                                    unsigned __int64 Newval, unsigned __int64 Comparand);
```

Atomic Compare and Exchange (`_InterlockedCompareExchange64_rel`)

This function is the same as the `_InterlockedCompareExchange_rel` function, except that those parts of the algorithm that are marked "Atomic" are performed by the `cmpxchg8.rel` instruction.

This function has the following format:

```
unsigned __int64  _InterlockedCompareExchange64_rel (volatile unsigned __int64 *Destination,  
                                                     unsigned __int64 Newval, unsigned __int64 Comparand);
```

Conditional Atomic Compare and Exchange Longword (`__CMP_SWAP_LONG`)

The `__CMP_SWAP_LONG` function performs a conditional atomic compare and exchange operation on a longword. The longword pointed to by *source* is read and compared with the longword *old_value*. If they are equal, the longword *new_value* is written into the longword pointed to by *source*. The read and write is performed atomically, with no intervening access to the same memory region.

The function returns 1 if the write occurs, and 0 otherwise.

This function has the following format:

```
int  __CMP_SWAP_LONG (volatile void *source, int old_value, int new_value);
```

source

The longword value to be compared with *old_value*.

old_value

The longword value *source* is compared with.

new_value

The longword value written into *source* if *source* and *old_value* are equal.

Conditional Atomic Compare and Exchange Quadword (`__CMP_SWAP_QUAD`)

The `__CMP_SWAP_QUAD` function performs a conditional atomic compare and exchange operation on a quadword. The quadword pointed to by *source* is read and compared with the quadword *old_value*. If they are equal, the quadword *new_value* is written into the quadword pointed to by *source*. The read and write is performed atomically, with no intervening access to the same memory region.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

The function returns 1 if the write occurs, and 0 otherwise.

This function has the following format:

```
int __CMP_SWAP_QUAD (volatile void *source, int old_value, int new_value);
```

source

The quadword value to be compared with *old_value*.

old_value

The quadword value *source* is compared with.

new_value

The quadword value written to *source* if *source* and *old_value* are equal.

Conditional Atomic Compare and Exchange Longword with Acquire Semantics (__CMP_SWAP_LONG_ACQ)

The `__CMP_SWAP_LONG_ACQ` function performs a conditional atomic compare and exchange operation with acquire semantics on a longword. The longword pointed to by *source* is read and compared with the longword *old_value*. If they are equal, the longword *new_value* is written into the longword pointed to by *source*. The read and write is performed atomically, with no intervening access to the same memory region.

Acquire memory ordering guarantees that the memory read/write is made visible *before* all subsequent data accesses to the same memory location by other processors.

The function returns 1 if the write occurs, and 0 otherwise.

This function has the following format:

```
int __CMP_SWAP_LONG_ACQ (volatile void *source, int old_value, int new_value);
```

source

The longword value to be compared with *old_value*.

old_value

The longword value *source* is compared with.

new_value

The longword value written into *source* if *source* and *old_value* are equal.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

Conditional Atomic Compare and Exchange Quadword with Acquire Semantics (`__CMP_SWAP_QUAD_ACQ`)

The `__CMP_SWAP_QUAD_ACQ` function performs a conditional atomic compare and exchange operation with acquire semantics on a quadword. The quadword pointed to by *source* is read and compared with the quadword *old_value*. If they are equal, the quadword *new_value* is written into the quadword pointed to by *source*. The read and write is performed atomically, with no intervening access to the same memory region.

Acquire memory ordering guarantees that the memory read/write is made visible *before* all subsequent memory data accesses to the same memory location by other processors.

The function returns 1 if the write occurs, and 0 otherwise.

This function has the following format:

```
int __CMP_SWAP_QUAD_ACQ (volatile void *source, int old_value, int new_value);
```

source

The quadword value to be compared with *old_value*.

old_value

The quadword value *source* is compared with.

new_value

The quadword value written into *source* if *source* and *old_value* are equal.

Conditional Atomic Compare and Exchange Longword with Release Semantics (`__CMP_SWAP_LONG_REL`)

The `__CMP_SWAP_LONG_REL` function performs a conditional atomic compare and exchange operation with release semantics on a longword. The longword pointed to by *source* is read and compared with the longword *old_value*. If they are equal, the longword *new_value* is written into the longword pointed to by *source*. The read and write is performed atomically, with no intervening access to the same memory region.

Release memory ordering guarantees that the memory read/write is made visible *after* all previous data memory accesses to the same memory location by other processors.

The function returns 1 if the write occurs, and 0 otherwise.

This function has the following format:

```
int __CMP_SWAP_LONG_REL (volatile void *source, int old_value, int new_value);
```

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

source

The longword value to be compared with *old_value*.

old_value

The longword value *source* is compared with.

new_value

The longword value written into *source* if *source* and *old_value* are equal.

Conditional Atomic Compare and Exchange Quadword with Release Semantics (`__CMP_SWAP_QUAD_REL`)

The `__CMP_SWAP_QUAD_REL` function performs a conditional atomic compare and exchange operation with release semantics on a quadword. The quadword pointed to by *source* is read and compared with the quadword *old_value*. If they are equal, the quadword *new_value* is written into the quadword pointed to by *source*. The read and write is performed atomically, with no intervening access to the same memory region.

Release memory ordering guarantees that the memory read/write is made visible *after* all previous data memory accesses to the same memory location by other processors.

The function returns 1 if the write occurs, and 0 otherwise.

This function has the following format:

```
int __CMP_SWAP_QUAD_REL (volatile void *source, int old_value, int new_value);
```

source

The quadword value to be compared with *old_value*.

old_value

The quadword value *source* is compared with.

new_value

The quadword value written into *source* if *source* and *old_value* are equal.

Return Address (`__RETURN_ADDRESS`)

The `__RETURN_ADDRESS` function produces the address to which the function containing the built-in call will return as a 64-bit integer (on Alpha systems, the value of R26 on entry to the function; on I64 systems, the value of B0 on entry to the function).

This built-in function cannot be used within a function specified to use nonstandard linkage.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

This function has the following format:

```
__int64 __RETURN_ADDRESS (void);
```

Implement Alpha `__PAL_GENTRAP` and `__PAL_BUGCHK` Builtins (`__break2`)

The `__break2` function is used to implement the Alpha `__PAL_GENTRAP` and `__PAL_BUGCHK` built-in functions on OpenVMS I64 systems.

The `__break2` function is equivalent to the `__break` function with the second parameter passed in general register 17:

```
R17 = __R17_value; __break (__break_code);
```

This function has the following format:

```
void __break2 (__Integer_Constant __break_code, unsigned __int64 __r17_value);
```

`__breakcode`

The particular software condition that has occurred.

`__r17_value`

The value of R17, a volatile general register reserved by the OpenVMS Itanium calling standard for use by compiled code to communicate with specialized compiler support routines that require out-of-band information passing.

Flush Register Stack (`__flushrs`)

The `__flushrs` function flushes the register stack.

This function has the following format:

```
void __flushrs (void);
```

Load Register Stack (`__loadrs`)

The `__loadrs` function loads the register stack.

This function has the following format:

```
void __loadrs (void);
```

Probe Read-Access Permission (`__prober`)

The `__prober` function determines whether read access to the virtual address specified by `__address` bits {60:0} and the region register indexed by `__address` bits {63:61} is permitted at the privilege level given by `__mode` bits {1:0}. It returns 1 if the access is permitted, and 0 otherwise.

This function can probe only with equal or lower privilege levels. If the specified privilege level is higher (lower number), then the probe is performed with the current privilege level.

This function is the same as the Intel `__probe_r` function.

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

This function has the following format:

```
int __prober (__int64 __address, unsigned int __mode);
```

__address

Virtual address for which read-access permission is being checked.

__mode

Privilege level for which read-access permission is being checked.

Probe Write-Access Permission (__probew)

The __probew function determines whether write access to the virtual address specified by __address bits {60:0} and the region register indexed by __address bits {63:61}, is permitted at the privilege level given by __mode bits {1:0}. It returns 1 if the access is permitted, and 0 otherwise.

This function can probe only with equal or lower privilege levels. If the specified privilege level is higher (lower number), then the probe is performed with the current privilege level.

This function is the same as the Intel __probe_w function.

This function has the following format:

```
int __probew (__int64 __address, unsigned int __mode);
```

__address

Virtual address for which write-access permission is being checked.

__mode

Privilege level for which write-access permission is being checked.

Translation Access Key (__tak)

The __tak function returns the translation access key.

This function has the following format:

```
unsigned int __tak (__int64 __address);
```

__address

Virtual address for translation key is being returned.

Translate to Physical Address (__tpa)

The __tpa function translates a virtual address to a physical address.

This function has the following format:

```
__int64 __tpa(__int64 __address);
```

Built-In Functions

C.2 Built-In Functions for I64 Systems *(I64 only)*

__address

Virtual address to be translated.

D

Class Library Restrictions

This appendix describes known problems and restrictions for the Class Library. Please note that **String Package**, which is part of the Class Library, is entirely different from the `String` class that is part of the newly-implemented C++ Standard Library and known as the **String Library**. Do not confuse these two contrasting implementations.

D.1 Class Library Restrictions

The following are restrictions in the C++ Class Library:

- No Class Library support for 128-bit long doubles
The Class Library does not include support for 128-bit long doubles.
- Conflict with redefinition of `clear()`
If your program includes both `< curses.h>` and `< iostream.hxx>`, HP C++ might fail to compile your program because `clear()` is defined by both header files. In `< curses.h>`, `clear()` is defined as a macro whereas in `< iostream.hxx>` `clear()` is defined as a member function.
Workarounds:
If your program does not use either `clear()` or uses the `< curses.h>` `clear()`, include the `< iostream.hxx>` header first, followed by `< curses.h>`.
If your program uses the `ios::clear()` function, undefine the `clear()` macro directly after the `#include < curses.h>` statement.
- On OpenVMS Alpha systems, class library `IOStreams` do not support denormalized IEEE numbers. The workaround is to use C Run-Time Library functions like `printf` and `scanf` instead.

E

Compiler Compatibility

This appendix describes HP C++ compatibility with other C++ compilers, and documents compatibility concerns between the Version 5.*n* and Version 6.*n* compilers.

For porting and compatibility between Alpha and I64 systems, see Chapter 4.

HP C++ implements the C++ International Standard, with some differences, as described in the online release notes in:

```
SYS$HELP:CXX_RELEASE_NOTES.PS
```

This language differs significantly from *The Annotated C++ Reference Manual*, implemented by the Version 5.*n* compilers. When switching from a Version 5.*n* compiler, you might need to modify your source files, especially if you use the default language mode. In addition, language changes can affect the run-time behavior of your programs. If you want to compile existing source code with minimal source changes, compile using the `/STANDARD=ARM` qualifier option. See Chapter 7 for information on and changes to the Standard Library.

This chapter describes ways to avoid having the compiler reject program code that previously worked with other C++ implementations that adhere less strictly to the C++ language definition. References to applicable portions of *The C++ Programming Language, 3rd Edition* indicate where you can find additional help.

E.1 Compatibility with Other C++ Compilers

In default mode (`/STANDARD=RELAXED`), the compiler implements most features of the C++ International Standard, including:

- Run-time type identification (RTTI), with `dynamic_cast` and the `typeid` operator (see Section 2.4)
- New-style casts (`static_cast`, `reinterpret_cast`, and `const_cast`)
- Array new and delete

Compiler Compatibility

E.1 Compatibility with Other C++ Compilers

For compatibility with previous versions, the compiler provides the following language mode options:

/STANDARD=RELAXED

Specify this option if you want an ANSI C++ compiler that supports some commonly used extensions and is somewhat less strict than the standard. This is the default compiler mode. Please note that `/STANDARD=ANSI` is accepted as a synonym for `/STANDARD=RELAXED` to be compatible with previous compiler versions.

If you want to use `RELAXED` mode but find that the compiler generates too many diagnostics in that mode, you can use the `/QUIET` option with the `/STANDARD=RELAXED` option. The `/QUIET` option relaxes error checking and suppresses or reduces the severity of many diagnostics. It also suppresses many warnings that are generated in `RELAXED` mode but were not issued by Version 5.*n* compilers. For information on message control options, see Section 2.5.

/STANDARD=ARM

Specify this option if you want to compile programs developed using Version 5.*n* and want to minimize source changes.

HP C++ Version 6.*n* and higher also provides support for other C++ dialects and language modes. You can specify the following options:

/STANDARD=MS

Specify this option if you want the compiler to accept additional Microsoft Visual C++ extensions.

/STANDARD=STRICT_ANSI

Enforce the ANSI standard strictly but permit some ANSI violations that should be errors to be warnings. To force ANSI violations to be issued with Error instead of Warning severity, use `/WARNINGS=ANSI_ERRORS` in addition to `/STANDARD=STRICT_ANSI`.

/STANDARD=LATEST

Use the latest C standard dialect. `/STANDARD=LATEST` is currently equivalent to `/STANDARD=C99`, but is subject to change when newer versions of the C standard are released.

With `/STANDARD=MS` you may also want to specify `/QUIET` to reduce the number of diagnostic messages generated.

E.2 Compatibility with Version 5.6 and Earlier

This section provides details about differences between the Version 6.*n* and later compilers, and the Version 5.6 and earlier compilers:

- Language differences
- Implementation differences
- Library differences

E.2.1 Language Differences

Users should be aware of the following language differences between Version 6.*n* and higher (denoted simply as Version 6.*n* in the following list), and previous versions of the compiler.

- The most important language differences result from the current implementation of the C++ International Standard in the Version 6.*n* compilers. If you want to compile existing source code with minimal source changes, compile using the `/STANDARD=ARM` option.
- Because the Version 6.*n* compilers perform more error checking than previous versions, they generate significantly more diagnostic messages. However, you can use the `/QUIET` option to relax error checking and reduce the severity of many diagnostics. *Message Control and Information Options*.
- The following keywords, introduced with the C++ International Standard, are always reserved keywords in all compiler modes:

```
bool, const_cast, explicit, export, false, mutable, dynamic_cast,  
reinterpret_cast, static_cast, true, typeid, typename, wchar_t
```

Alternative representation keywords are as follows:

```
and, and_eq, bitand, bitor, compl, not, not_eq, or, or_eq, xor, xor_eq
```

- Taking the address of a bit field is not allowed in the current version.
- Creation of temporaries and their lifetimes vary among compiler modes.
- Macro expansion in pragmas can give different results in the current and previous versions.
- The following are distinct types in the Version 6.*n* compilers; they were the same type in previous versions:

Compiler Compatibility

E.2 Compatibility with Version 5.6 and Earlier

```
typedef void (*PF)(); // Pointer to an extern "C++" function
extern "C" typedef void (*PCF)(); // Pointer to an extern "C" function
void f(PF);
void f(PCF);
```

- Version 6.*n* does not allow converting a pointer to member from a derived class to a virtual base class.
- Calling a nonstatic member function through a null pointer is undefined behavior. Certain cases that used to run without errors in previous versions no longer run in the current version. For example:

```
#include <iostream.h>
struct A {
    int a;
};
struct D : public virtual A
{
    A* toA(){ return (A*) this; }
};
main ()
{
    D* d = NULL;
    A* ad = d->toA(); // will ACCVIO
    if (ad==NULL) cout << "ok";
}
```

- In Version 6.*n* compilers, `bool` is a built-in type. In previous versions, it is user-defined, typically as `int` in system header files. Mangling differs in this respect only for functions that have arguments of type `bool`.
In Version 6.*n* compilers, the size of `bool` is 1. In previous versions, `bool` is user defined, typically as `int` with a size of 4.
In Version 6.*n* compilers, the size of a boolean expression (`sizeof(a && b)`) is 1. In previous versions, the size is 4, independent of the size of `bool`.
- Version 6.*n* compilers do not cause pragmas to become effective within function bodies when scanning template definitions.
- Version 6.*n* compilers do not allow the “virtual” storage class modifier to be used with member function definitions outside a class.
- Version 6.*n* compilers do not allow declaration of pointers to members of type `void`. For example, the following is not allowed:

```
typedef void Z::* any_ptom;
```

Compiler Compatibility

E.2 Compatibility with Version 5.6 and Earlier

E.2.2 Implementation Differences

Users should be aware of the following implementation differences between Version 6.*n* compilers, and previous versions of the compiler:

- The automatic template instantiation model is different for Version 6.*n*, and previous compiler versions. See Section E.2.3 for details.

It is different yet again for I64 systems. See Chapter 5 for details.

- Version 6.*n* and higher drops qualifiers on parameters when determining the function type, as dictated by the C++ International Standard. For instance, in the following example, the function declarations are the same function.

```
f(const int p1);  
f(int p1);
```

For compatibility with previous versions, if qualifiers are included in function declarations, they are also included in the mangled name. (Note: this is not true for model ANSI or for I64 systems.)

- Version 6.*n* differs from previous versions in interpreting undefined behavior, as when incrementing takes effect in this example:

```
f(i++, i++);
```

- Version 6.*n* cannot handle a `#pragma define_template` that spans multiple lines without the backslash (\) delimiter. Version 5.6 can handle this without problems.
- Version 6.*n* displays `#line number` in `/PREPROCESS_ONLY` output. The previous version displays `#number`.
- After encountering an illegal multibyte character sequence, Version 6.*n* issues a warning diagnostic and continues processing. The previous version issues an error and stops processing.
- Version 6.*n* does not support VAX C module include syntax (for example, `#include acms$submitter` without `<>` or `" "` delimiters). The compiler searches text libraries for modules included using the normal include syntax (specifying the `" "` or `<>` delimiters) and correctly (according to the C++ standard) rejects `#include` directives that do not follow this syntax.

Compiler Compatibility

E.2 Compatibility with Version 5.6 and Earlier

E.2.3 Using Templates

The template instantiation model was completely redesigned for C++ Version 6.0. The changes include:

- Automatic template instantiation now occurs at compile time. Necessary templates are instantiated automatically by the compilation of the source file that needs them and has access to the template definitions.
- During automatic template instantiation, instantiations are written into the repository as object files. Compilation of instantiations is no longer done at link time.
- For automatic instantiation, the compiler no longer requires that template declarations and definitions appear in header files.
- `Template.map` files are no longer supported as a way to match template declarations and definitions.
- Several new manual template instantiation pragmas have been added.

The automatic template instantiation model new with Version 6.0 is not directly compatible with previous template instantiation mechanisms. When linking applications using Version 6.0 and later, instantiations might not be resolved from existing Version 5.*n* repositories. Where possible, it is safest to start fresh with an empty repository and create the required instantiations by compiling all source files. If this is not possible, there are some strategies that can be used to link mixed generation instantiations.

If you used both Version 6.*n* and Version 5.*n* to build applications, HP strongly recommends that you use different repositories to contain automatic template instantiations for Version 6.*n* and Version 5.*n* compilations. The default repository name is the same for Version 6.*n* as for prior versions. Thus, if you use Version 6.*n* with older pre-6.*n* versions, you should do compilations in a different directory for each compiler or explicitly specify a different repository for each using the `/REPOSITORY` qualifier.

E.2.3.1 Linking with Version 5.*n* Instantiations

When linking applications using Version 6.*n* against instantiations created with Version 5.*n*, it is necessary to complete the Version 5.*n* instantiation process, to create instantiation object files. If `old_repository` is a Version 5.*n* repository then you would create the Version 5.*n* instantiation object files by using the Version 5.*n* `cxxlink`:

```
CXXLINK/NOEXE /REPOSITORY=[old_repository]  
  <Version 5.n object files>
```

Compiler Compatibility

E.2 Compatibility with Version 5.6 and Earlier

<Version 5.*n* object files> are the object files that were created using the Version 5.*n* compiler; `old_repository` now contains the instantiation object files. Create a library of these object files as follows:

```
LIBRARY/CREATE/OBJECT lib_old_repository/LOG
LIBRARY/INSERT/OBJECT lib_old_repository/LOG
    [old_repository]*.obj
```

When linking using Version 6.*n*, specify `lib_old_repository.olb` after all of the Version 5.*n* object files that are being linked.

E.2.3.2 Linking Version 5.*n* Applications Against Version 6.*n* Repositories

In a similar way, you can create a library of Version 6.*n* instantiation object files to link into a Version 5.*n* application being linked using C++ Version 5.*n*. If `new_repository` is the Version 6.*n* repository, then a library of the instantiations would be created by:

```
LIBRARY/CREATE/OBJECT lib_new_repository/LOG
LIBRARY/INSERT/OBJECT lib_new_repository/LOG [new_repository]*.obj
```

When linking using Version 5.*n*, specify `lib_new_repository.olb` after all of the Version 6.*n* object files that are being linked.

E.2.4 Library Differences

Aspects of memory allocation and deallocation have changed from the V5.*n* and earlier compilers to the Version 6.*n* compilers. See the description of `/[NO]STDNEW` and `/[NO]GLOBAL_ARRAY_NEW` in *The C++ Standard Library*.

E.3 Using Classes

This section discusses porting issues pertaining to C++ classes.

E.3.1 Friend Declarations

When making friend declarations, use the elaborated form of type specifier. The following code fragment implements the legal and comments out the illegal friend declaration:

```
class Y;
class Z;
class X;
    //friend Y;  ** not legal
    friend class Z; // legal
};
```

Compiler Compatibility

E.3 Using Classes

E.3.2 Member Access

Unlike some older C++ implementations, HP C++ strictly enforces accessibility rules for public, protected, and private members of a base class. For more information, see *The C++ Programming Language, 3rd Edition*.

E.3.3 Base Class Initializers

Unlike some older C++ implementations, HP C++ requires you to use the base class name in the initializer for a derived class. The following code fragment implements a legal initializer and comments out an illegal initializer:

```
class Base {
    // ...
public:
    Base (int);
};
class Derived : public Base {
    // ...
public:
    // Derived(int i) : (i) { /* ... */ }    ** not legal
    Derived(int i) : Base(i) { /* ... */ } // ** legal, supplies class name
};
```

For more information, see *The C++ Programming Language, 3rd Edition*.

E.4 Undefined Global Symbols for Static Data Members

When a static data member is declared, the compiler issues a reference to the external identifier in the object code, which must be resolved by a definition. The compiler does not support the declaration anachronism shown in *The C++ Programming Language, 3rd Edition*.

For example, consider the following code fragment:

```
class C {
    static int i;
};
//missing definition
//int C::i = 5;
int main ()
{
    int x;
    x=C::i;
    return 0;
}
```

The compiler does not issue any messages during compilation; however, when you attempt to link a program containing this code, the linker issues an unresolved symbol error message for the variable `C::i`.

E.5 Functions and Function Declaration Considerations

HP C++ requires the use of function definitions as described in *The C++ Programming Language, 3rd Edition*. For examples of outdated syntax not allowed in HP C++, see *The C++ Programming Language, 3rd Edition*.

Because all linkage specifications for a name must agree, function prototypes are not permitted if the function is later declared as an inline function. The following code is an example of such a conflicting function declaration:

```
int f();  
inline int f() { return 1; }
```

In this example, `f` is declared with both internal and external linkage, which causes a compiler error.

E.6 Using Pointers

This section demonstrates how to use pointers effectively in HP C++.

E.6.1 Pointer Conversions

In HP C++, you cannot implicitly convert a `const` pointer to a nonconstant pointer. For example, `char *` and `const char *` are not equivalent; explicitly performing such a cast can lead to unexpected results.

For more information, see *The C++ Programming Language, 3rd Edition*.

E.6.2 Bound Pointers

Binding a pointer to a member function with a particular object as an argument to the function is not allowed in HP C++. For more information on the illegality of casting bound pointers, see *The C++ Programming Language, 3rd Edition*.

E.6.3 Constants in Function Returns

Because the return value cannot be an lvalue, the `const` keyword in a function return has no effect on the semantics of the return. However, using the `const` keyword in a function return does affect the type signature. For example:

```
static int f1( int a, int b) {;}  
const int (* const (f2[])) (int a, int b) = {f1};
```

In this example, the referenced type of the pointer value `f1` in the initializer for `f2[]` is *function* (signed int, signed int), which returns signed int. This is incompatible with *function* (signed int, signed int), which returns `const signed int`.

Compiler Compatibility

E.6 Using Pointers

You can omit the `const` of `int` because it affects only the constant return signature.

E.6.4 Pointers to Constants

The following example shows a type mismatch between a pointer to a `char` and a pointer to a `const char` that some other compilers might not find:

```
void foo (const char* argv[]) {}
int main()
{
    static char* args[2] = {"foo", "bar"};

    /* In this statement, the referenced type of the pointer value
       "args" is "pointer to char" which is not compatible with
       "pointer to const char" */

    foo (args);
    return 0;
}
```

You can correct this example by changing `static char` to `static const char`. Use an explicit type cast to get an argument match only if no other option is available; such a cast may break on some C++ implementations.

E.7 Using typedefs

Using a synonym after a class, struct, or union prefix is illegal. Using a synonym in the names for constructors and destructors within the class declaration itself is also illegal.

In the following example, the illegal typedef specifier is commented out:

```
typedef struct { /* . . . */ } foo;
// typedef struct foo foobar;          ** not legal
```

For more information, see *The C++ Programming Language, 3rd Edition*.

E.8 Initializing References

HP C++ warns against initializing nonconstant references to refer to temporary objects. The following example demonstrates the problems that can result:

```
static void f()
{
    int i = 5;
    i++;           // OK
    int &ri = 23;
    ri++;         // In the initializer for ri, the initialization of a
                  // non-const reference requires a temporary for "23".
}
```

Compiler Compatibility

E.8 Initializing References

The issue of reference initialization arises most often in assignment operators and in copy constructors. Wherever possible, declare all reference arguments as `const`.

For more information, see *The C++ Programming Language, 3rd Edition*.

E.9 Using the `switch` and `goto` Statements

Branching around a declaration with an explicit or implicit initializer is not legal, unless the declaration is in an inner block that is completely bypassed. To satisfy this constraint, enclose the declaration in a block. For example:

```
int i;
switch (i) {
case 1:
    int l = 0;    //not initialized at this case label
    myint m = 0; //not initialized at this case label
    {
        int j = 0;    // legal within the braces
        myint m = 0; // legal within the braces
    }
case 2:
    break;
// ...
}
```

For more information on using the `switch` statement, see *The C++ Programming Language, 3rd Edition*.

E.10 Using Volatile Objects

You must supply the meaning of copy constructing and assigning from volatile objects, because the compiler generates no copy constructors or assignment operators that copy or assign from volatile objects. The following example contains examples of such errors, as noted in the comments:

```
class A {
public:
    A() { }
    // A(volatile A&) { }
    // operator=(volatile A&) { return 0; }
};

void foo()
{
    volatile A va;
    A a;

    A cca(va); // error - cannot copy construct from volatile object
    a = va;    // error - cannot assign from volatile object
}
```

Compiler Compatibility

E.10 Using Volatile Objects

```
    return;  
}
```

For more information, see *The C++ Programming Language, 3rd Edition*.

E.11 Preprocessing

HP C++ allows identifiers, but not expressions, on the `#ifdef` preprocessor directive. For example:

```
// this is not legal  
// #ifdef KERNEL && !defined(__POSIX_SOURCE)
```

The following is the legal alternative:

```
// use this instead  
#if defined(KERNEL) && !defined(__POSIX_SOURCE)
```

For more information, see *The C++ Programming Language, 3rd Edition*.

E.12 Managing Memory

The proper way to manage memory for a class is to overload the `new` and `delete` operators. This is in contrast to some older C++ implementations, which let you manage memory through assignment to the `this` pointer.

For more information, see *The C++ Programming Language, 3rd Edition*.

Program developers must take care that any user-defined `new` operators always return pointers to quadword-aligned memory.

E.13 Size-of-Array Argument to delete Operator

If a size-of-array argument accompanies a `delete` operator, HP C++ ignores the argument and issues a warning. The following example includes an anachronistic use of the `delete` operator:

```
int main()  
{  
    int *a = new int [20];  
    int *b = new int [20];  
    delete[20] a;    //old-style; argument ignored, warning issued  
    delete[] b;  
return 0;  
}
```

E.14 Flushing the Output Buffer

Do not depend on the newline character (`\n`) to flush your terminal output buffer. A previous stream implementation might have done so, but this behavior is not in conformance with Version 2.0 of the AT&T `iostream` library. If you want to flush the output buffer, use the `endl` manipulator or the `flush` member function.

E.15 Linking

When linking applications, use `CXXLINK` instead of `LINK`. See Section 1.3 (*Alpha only*) and Section 1.4 (*164 only*).

E.16 Incrementing Enumerations

Some other C++ implementations let you perform integer arithmetic, including `++`, on enumerated types; HP C++ does not allow this.

E.17 Guidelines for Writing Clean 64-Bit Code

Paying careful attention to data types can ensure that your code works on both 32-bit and 64-bit systems. Use the following guidelines to write clean 64-bit code:

- Variables that should be 32 bits in size on both 32-bit systems and 64-bit OpenVMS Alpha systems should be declared as `int` (not `long`).
- If you want 32-bit variables on a 32-bit system and an OpenVMS system, declare them as `int`.
- A 64-bit number on OpenVMS must be declared as `__int64` or `long long`.
- Remember that register variables and unsigned variables default to `int` (32 bits).
- Constants are 32-bit quantities by default. Performing shift operations or bit operations on constants will give 32-bit results. You must add `L` to the constant to get a 64-bit result. For example:

```
long foo, bar;  
foo = 1L << bar;
```

- Assigning to a `char` is not atomic on OpenVMS Alpha systems. You will get a load of 32 or 64 bits, followed by byte operations to extract, mask, and shift the byte, followed by a store of 32 or 64 bits.
- Bit-fields declared as `int` on OpenVMS Alpha systems generate load/store 32 bits. Bit-fields declared as `long` on OpenVMS Alpha systems generate load/store 64 bits.

Compiler Compatibility

E.17 Guidelines for Writing Clean 64-Bit Code

- If you do not explicitly declare the formal parameters to functions, their sizes may not match the caller sizes. The default is `int`, which truncates 64-bit addresses.
- The `%d` and `%x` format specifiers print 32 bits of data. Use `%Ld` or `%Lx` with `printf` to print 64 bits of data. You can use `%p` on both 32- and 64-bit systems to print the value of pointers.

- CXX command format, 1-3

- error messages, 1-4 to 1-5

Compiler (cont'd)

template

- advanced program development, 5–16
- automatic instantiation, 5–10
- compatibility with earlier versions, E–6
- creating common instantiation library, 5–18
- creating libraries, 5–14
- dependency management, 5–18
- implicit inclusion, 5–16
- linking Version 5.*n* applications
 - against Version 6.*n* repositories, E–7
- linking with Version 5.*n* instantiations, E–6
- mixing automatic and manual instantiation, 5–4
- overview, 5–1
- repositories, 5–15
- template instantiation qualifiers, 5–9, 5–21
- using, 1–3

Constant

- in function returns, E–9
- pointer to, E–10

Constructs, debugger supported

- in address expressions, 8–5
- in language expressions, 8–5

Conversion

- explicit type, 2–28
- floating-point number, 2–27
- integer, 2–27
- pointer, E–9

Conversion operators

- debugger referencing, 8–12

Copy sign built-in functions, C–37

- `__COS` built-in function, C–38
- `cplusplus` macro, 2–18
- `__CPYS` built-in function, C–37
- `__CPYSE` built-in function, C–37
- `__CPYSEF` built-in function, C–37

- `__CPYSF` built-in function, C–37
- `__CPYSN` built-in function, C–37
- `__CPYSNF` built-in function, C–37
- `__CVTGF_C` built-in function, C–38
- `__CVTGFQ` built-in function, C–39
- `__CVTTQ` built-in function, C–39
- `__CVTTS_C` built-in function, C–39
- `cxx` command
 - format, 1–3
- `CXX` command
 - qualifiers for, A–1
- `CXXLINK` command, 1–5, 1–10
- `CXXLINK` facility, 1–5, 1–10
 - interaction with OpenVMS Linker qualifiers, 1–6
- `[cxx_repository]` directory, 5–10
- `[cxx_repository]` instantiation file, 5–10

D

`dasm` intrinsic function, C–3

Data members

- nonstatic, 8–6 to 8–7

Data types

- predefined for debugger support, 8–5

`DATE` macro, 2–18

Debugger, 8–1 to 8–15

- command-line options, 8–3

Debugger commands

- `deposit/type`, 8–10
- `examine/type`, 8–10
- `set language c_plus_plus`, 8–3
- `show language`, 8–3

Debugger referencing

- by type, 8–10
- conversion operators, 8–12
- destructors, 8–12
- function arguments
 - `this`, `*this`, and `this->`, 8–13
- nonstatic data members, 8–7
- pointer and reference types, 8–12
- reference members, 8–7
- reference objects, 8–7

- Debugging
 - preparation for, 8-1
- /DEBUG qualifier, 8-2, 8-3
 - with RUN command, 1-12
- DECCXX macro, 2-18
- DECCXX_VER macro, 2-20
- __DECC_INCLUDE_EPILOGUE.H file, 9-10
- __DECC_INCLUDE_PROLOGUE.H file, 9-10
- DEC Language-Sensitive Editor (LSE), 1-1, B-1 to B-4
- Declaration
 - asm, 2-29
- Declarations
 - friend, E-7
- DEC Source Code Analyzer (SCA), B-4
- DEC Text Processing Utility (DECTPU)
 - See DECTPU
- DECTPU, 1-1
 - using, 1-3
- /DEFINE=__FORCE_INSTANTIATIONS qualifier, A-13
- /DEFINE=__[NO_]USE_STD_Iostream qualifier, A-14
- /DEFINE qualifier, A-13
- delete operator
 - overriding global, 1-8
 - size-of-array argument to, E-12
- Demangler
 - CXXDEMANGLE command format, 1-16
- deposit/type debugger command, 8-10
- Destructors
 - debugger referencing, 8-12
- /DIAGNOSTICS qualifier, A-14
- /DISTINGUISH_NESTED_ENUMS qualifier, A-14
- __DIVF_C built-in function, C-36
- __DIVG_C built-in function, C-36
- Division operator, 2-28
- __DIVS_C built-in function, C-36
- __DIVT_C built-in function, C-36

- Double-precision, floating-point arithmetic
 - built-in functions, C-36
- __dsrlz built-in function, C-52
- D_FLOAT macro, 2-20

E

- echo DCL command, 1-14
- Editor
 - DEC Language-Sensitive Editor (LSE), 1-1, B-1 to B-4
 - DECTPU, 1-1, 1-3
 - EVE interface, 1-3
- /ENDIAN qualifier, A-14
- Enumerated types
 - incrementing, E-13
- envp
 - main function argument, 1-13
- Epilogue/prologue files, 9-10
- Equality operators, 2-29
- Error messages
 - compiler, 1-4 to 1-5
 - linker, 1-9 to 1-10
- Errors
 - run-time, 1-13
- /ERROR_LIMIT qualifier, A-14
- EVE interface
 - to DECTPU, 1-3
- examine/type debugger command, 8-10
- EXCEPTIONS macro, 2-22, A-17
- /EXCEPTIONS qualifier, A-15
- Explicit type conversion, 2-28
- Explicit type conversion, language extension, 2-28
- External name encoding, 2-25, 2-26
- extern specifier, 3-3
- /EXTERN_MODEL qualifier, A-17

F

- __FABS built-in function, C-39
- fasm intrinsic function, C-3
- __fc built-in function, C-52

- File inclusion directive, #include, 2-35, 2-39
- FILE_ macro, 2-18
- /FIRST_INCLUDE qualifier, A-17
- Floating-point arithmetic built-in functions, C-36
- Floating-point number
 - converting to and from an integer, 2-27
- /FLOAT qualifier, A-18
- __flushrs built-in function, C-63
- FORCE_INSTANTIATIONS macro, 2-22
- Foreign command
 - for passing command-line arguments, 1-14
- Friend declarations, E-7
- Function
 - constant in returns, E-9
 - definitions, E-9
- Function arguments, this, *this, and this->
 - debugger referencing, 8-13
- Function returns
 - constants in, E-9
- Functions, E-9
 - debugger referencing, 8-11 to 8-13
- __fwb built-in function, C-52

G

- __getIndReg built-in function, C-51
- __getReg built-in function, C-48
- GLOBAL_ARRAY_NEW macro, 2-22, A-8
- goto statement, E-11
- /GRANULARITY qualifier, A-18
- Guiding declarations, 2-41
- G_FLOAT macro, 2-20

H

- Header file
 - implicit inclusion, 3-8
 - implicit inclusion in, 3-8
 - <stdarg.h>, 3-5
 - <varargs.h>, 3-5

- Header files
 - modifying, 3-2, 3-5
- HIDE_FORBIDDEN_NAMES macro, 2-22
- __HIDE_FORBIDDEN_NAMES macro, A-37

I

- ia64 macros, 2-19
- Identifier, 2-24
- IEEE_FLOAT macro, 2-18, 2-20
- IEEE_FP macro, 2-20, 2-22
- /IEEE_MODE qualifier, A-19
- #ifdef preprocessor directive, E-12
- Implementation extensions and features, 2-24, 2-27
- Implicit inclusion, 3-8
 - template, 5-16
 - automatic instantiation, 5-10
 - defining file extensions, 5-17
- /IMPLICIT_INCLUDE qualifier, A-20
- IMPLICIT_INCLUDE_ENABLED macro, 2-22
- IMPLICIT_USING_STD Macro
 - defined by command line qualifier
 - __IMPLICIT_USING_STD, 2-22
- #include directive, 2-35, 2-39
- /INCLUDE_DIRECTORY qualifier, 2-35, 2-39, A-21
- Initializers
 - using base class name with, E-8
- Initializing references, E-10
- INITIAL_POINTER_SIZE macro, 9-6
- Instantiation
 - automatic
 - linking with, 5-13
 - directives, 5-4
 - #pragma define_template, 5-4
 - #pragma do_not_instantiate, 5-8
 - #pragma instantiate, 5-8
 - manual, 5-3
 - mixed automatic and manual, 5-4
 - template, 5-1 to 5-24

Instantiation file, 5–10 to 5–13

Integer

converting to and from a floating-point number, 2–27

`_InterlockedCompareExchange64_acq` built-in function, C–58

`_InterlockedCompareExchange64_rel` built-in function, C–59

`_InterlockedCompareExchange_acq` built-in function, C–57

`_InterlockedCompareExchange_rel` built-in function, C–58

`__INTERLOCKED_TESTBITCC_QUAD` built-in function, C–40

`__INTERLOCKED_TESTBITSS_QUAD` built-in function, C–41

Intrinsic functions

asm, C–3

dasm, C–3

fasm, C–3

`__invala` built-in function, C–52

`__invalat` built-in function, C–52

`__isrlz` built-in function, C–53

`__itcd` built-in function, C–53

`__itci` built-in function, C–53

`__itrd` built-in function, C–53

`__itri` built-in function, C–54

K

Keywords

conflict resolution, 3–3

L

`__LABS` built-in function, C–42

Language expressions

supported constructs in, 8–5

Language mode

determining for debugger, 8–3

LATEST mode, E–2

Layout

class, 2–30, 2–32

of class object, 2–32

Leading Zeros built-in function, C–41

`_leadz` built-in function, C–41

`/LIBRARY` qualifier, A–25

Limits

numerical, 2–23

translation, 2–23

`LINE__` macro, 2–18

`/LINE_DIRECTIVES` Qualifier, A–25

Linkage

between C and C++, 3–3

specification, 2–30, 3–6

Linkage specifications, 3–6

Link compatibility, 3–14

Linker

command-line qualifiers, 1–9

error messages, 1–9 to 1–10

Linker (*Alpha only*), 1–5

Linker (*164 only*), 1–10

`/LIST` qualifier, A–25

`__loadrs` built-in function, C–63

`__LOCK_LONG` built-in function, C–42

Long names

modification by compiler, 2–26

LSE

See DEC Language-Sensitive Editor

`/L_DOUBLE_SIZE` qualifier, A–24

M

`/MACHINE_CODE` qualifier, A–25

Macro

Alpha system

`__alpha`, 2–19

`__ALPHA`, 2–19

`__ALPHA_AXP`, 2–19

`__32BITS`, 2–19

`__BOOL_EXISTS`, 2–18

`__BOOL_IS_A_RESERVED_WORD`, 2–18

`__DATE_`, 2–18

defined by command line qualifier

`__ALTERNATIVE_TOKENS`, 2–22

`__BIASED_FLT_ROUNDINGS`, 2–22

`__EXCEPTIONS`, 2–22, A–17

`__FORCE_INSTANTIATIONS`, 2–22

Macro

defined by command line qualifier (cont'd)

C-25
Remainder operator, 2-28
`/REPOSITORY` qualifier, 1-18, A-38
`required_pointer_size` pragma, 9-6
`__RETURN_ADDRESS` built-in function,
C-62
`/ROUNDING_MODE` qualifier, A-38
`__RPCC` built-in function, C-43
`__rsm` built-in function, C-56
RTTI macro, 2-22, A-39
`/RTTI` qualifier, A-39
`__rum` built-in function, C-56
run command, 1-12
Run compatibility, 3-16
Running programs, 1-12
Run-time errors, 1-13

S

Scope rules
 differences between ANSI C and C++,
 3-4
`__setIndReg` built-in function, C-51
`set language c_plus_plus` debugger
 command, 8-3
`__setReg` built-in function, C-50
Shareable images, creating, 3-12, 3-13
`/SHARE_GLOBALS` qualifier, A-39
Shift operators, 2-29
show language debugger command, 8-3

- /SHOW qualifier, A-40
- __SIN built-in function, C-44
- Single-precision, floating-point arithmetic
 - built-in functions, C-36
- Size-of-array argument
 - to delete operator, E-12
- sizeof operator, 2-28
- Source compatibility, 3-14
- Specifiers
 - access, 2-31
 - extern, 3-3
 - type, 2-29
 - typedef, E-10
- __ssm built-in function, C-56
- /STANDARD=ANSI mode, E-1
- /STANDARD=RELAXED mode, E-1
- Standard Library, 1-1
 - building programs with, 7-11
 - compatibility issues, 7-2 to 7-11
 - global array new and delete, 7-10
 - IOSTREAMS, 7-11
 - /[NO]USING_STD compatibility
 - qualifier, 7-3
 - overriding operator(new), 7-7, 7-9
 - pre-ANSI/ANSI iostreams
 - compatibility, 7-3
 - pre-ANSI and ANSI operator(new), 7-6
 - using RMS attributes with iostreams, 7-13
- /STANDARD qualifier
 - compiler, A-40
- Standard Template Library
 - building programs with, 7-11
 - using RMS attributes with iostreams, 7-13
- Statement
 - goto, E-11
 - switch, E-11
- Static object initialization
 - order of, 2-27
- <stdarg.h> header file, 3-5
- STD_ANDI macro, 2-22, A-41
- STD_ARM macro, 2-22, A-41
- STD_GNU macro, 2-22, A-41
- STD_MS macro, 2-22, A-42
- STD_NEW macro, 2-22
- STD_STRICT_ANSI macro, 2-22, A-42
- STD_STRICT_ANSI_ERRORS macro, 2-22, A-42
- STRICT_ANSI mode, E-2
- String Library
 - building programs with, 7-11
 - iostreams
 - using RMS attributes with, 7-13
- Structure alignment
 - of class, 2-30
- __SUBF_C built-in function, C-36
- __SUBG_C built-in function, C-36
- Subobject allocation
 - class, 2-32
- Subobject offsets
 - class, 2-31
- __SUBS_C built-in function, C-36
- __SUBT_C built-in function, C-36
- __sum built-in function, C-56
- switch statement, E-11
- __synci built-in function, C-57
- Syntax
 - main function, 1-13

T

- __tak built-in function, C-64
- Template
 - compatibility with earlier versions, E-6
- Template instantiation, 5-1 to 5-24
- /TEMPLATE_DEFINE qualifier, A-42
- Temporary objects, 2-33, 2-35
 - handling destruction after static member function call, 2-35
- __TESTBITCCI built-in function, C-44
- __TESTBITSSI built-in function, C-45
- __thash built-in function, C-57
- this function argument
 - debugger referencing, 8-13

this pointer
 assignment to, E-12
Thread safety, 7-11
TIME__ macro, 2-18
__tpa built-in function, C-64
Traceback information, 1-13
Trailing Zeros built-in function, C-45
__trailz built-in function, C-45
Translation limits, 2-23
Translation macros, C-2
__TRAPB built-in function, C-45
__ttag built-in function, C-57
Type conversion
 explicit, 2-28
typedef specifier, E-10
Type specifier
 volatile, 2-29

U

__UMLH built-in function, C-45
/UNDEFINE qualifier, A-42
__UNLOCK_LONG built-in function, C-42
/UNSIGNED_CHAR qualifier, A-42
User-defined operators, 8-13
USE_STD_Iostream macro, 2-22, A-42

USING_STD macro, 2-22
/USING_STD qualifier, A-43

V

<varargs.h> header file, 3-5
Variable-length argument list, 3-5
/VERSION qualifier, A-43
vms macro, 2-18
VMS macro, 2-18
VMS_VER macro, 2-20
vms_version macro, 2-20
VMS_VERSION macro, 2-20
Volatile object, E-11
volatile type specifier, 2-29

W

/WARNINGS qualifier, A-43
WCHAR_T__ macro, 2-18

X

/XREF qualifier, A-45
X_FLOAT macro, 2-20, 2-22, A-25
