

# Cognitive Psychology

PSYC230

Lecture # 11

*How is information stored in the mind?*

*What is the "unit of thought"?*

A word?

An image?

A logical proposition?

One of the oldest questions  
in psychology

Knowledge Representation

*What does memory research tell us?*

Different kinds of encoding processes  
appear to produce different kinds of memories

Maintenance rehearsal  
Distributed practice,  
acoustic interference

Elaborative rehearsal  
Meaningfulness &  
depth of processing

Different patterns of forgetting suggest different  
types of memories

Tulving's (1985) model

**Procedural Memory**  
frames & scripts

Knowing how: to ride a bicycle,  
play the piano, sign your name, etc

**Declarative Memory**

**Episodic**

**Semantic**

Knowing that: facts about your past (context-bound)  
and facts about the world (context-free)

## Procedural Knowledge

usually skilled motor sequences

How to: ride a bicycle, play the piano, sign your name, etc  
Stored as scripts (procedures) and frames

Formed as a result of process of proceduralisation  
the shift from slow, explicit information about  
procedures to rapid, implicit implementation  
of open-loop procedures

We have lots of automatic scripts & procedures  
we learn them very young

*bedtime script, school script, doctor's office script  
shower procedure, bicycle procedure, etc.*

## Procedural Knowledge

Requires no processing resources  
or awareness to access information  
an implicit, automatic memory process

Subject to various action slips  
e.g., *Putting the coffee grinder in the fridge*

May be a separate memory system,  
amnesiacs with declarative memory deficits  
often have no deficits in procedural memory

## Declarative Knowledge “Knowing that”

Declarative knowledge can be acquired *tacitly*  
(e.g., learning word meanings and grammar)

or *overtly* (e.g., times tables)

We are explicitly aware of  
two types of information

**Episodic:** Personally experienced events

**Semantic:** World knowledge, language, & concepts

## Episodic Memories

*Autobiographical Memories*

personally experienced events

Contextually-bound information

arranged in a hierarchy

Lifetime periods

major ongoing situations, living with  
someone, a particular job, etc

General events

repeated or extended events, birthdays, vacations

Specific events

images, feelings, details from events lasting  
seconds to hours

## Episodic Memories

personal memories of people, places, & events organised by context

Childhood amnesia -- almost total lack  
of memories from the first 5 years of life  
Reminiscence bump -- a large number of  
memories from the years between 15 & 25  
Retention function -- memories  
from recent past, recently exercised

The effects of age of emigration on  
the reminiscence bump  
● emigrated ages 20 - 24  
■ emigrated ages 34 - 35

Cognitive Change Hypothesis – periods  
of rapid change followed by stability  
lead to better encoding

Schrauf & Rubin (1998)

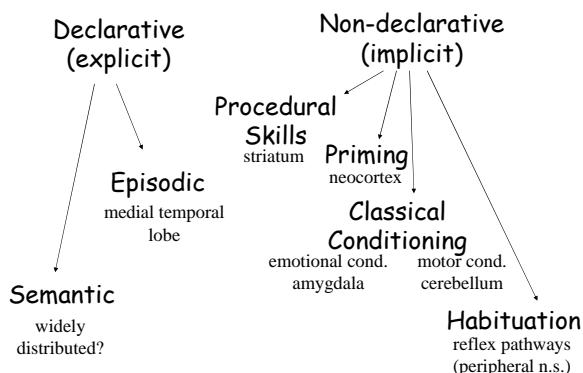

## Semantic Memory

world knowledge, language, & concepts

Organised in terms of meanings &  
relationships -- not dependent on context

Hippocampus appears to gradually consolidate new  
information with established cortical/structural  
memories, results in permanent, generalised memories

## Taxonomy & Anatomy of Memory

## Is memory the same as knowledge?

Some information isn't stored in  
memory at all,  
but we can still answer correctly

We use **knowledge** to compute  
information that we do not have stored

The relationship between stored facts  
(memories) is every bit as important as the  
facts themselves

## Semantic Memory / Knowledge (world facts)

Network of “fact nodes” interrelated  
by logical connections

Information exercised in so many  
different places & times it  
has become context free

## Semantic Memory / Knowledge world knowledge, language, & concepts

Organised in terms of meanings &  
relationships -- not dependent on context

### Theories of Semantic Memory Representation

Hierarchical Network Theory  
(semantic network model)

Prototype Theory

Exemplar Theory

Feature Comparison Theory

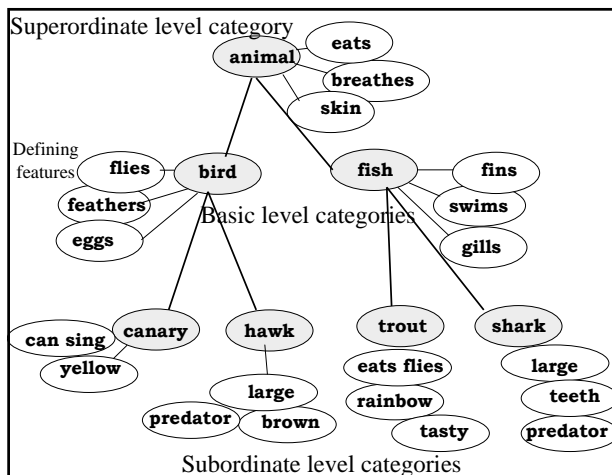

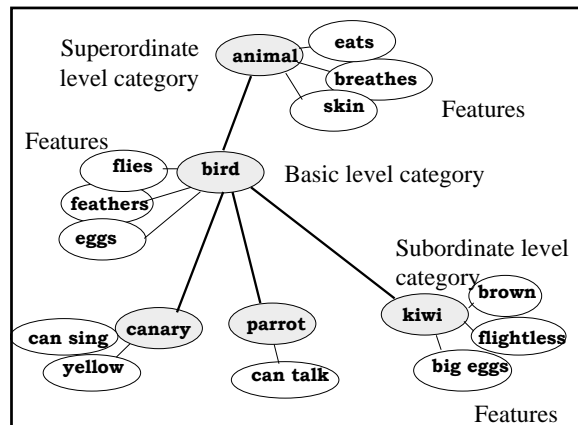

## Hierarchical Network Theory Collins & Quillian (1969)

Knowledge in semantic memory is stored as a  
network of nodes interrelated via  
propositional (logical) connections

Category: a group of objects or events  
(like a schema)

Individual instances are called *exemplars*

Each category has a set of necessary and sufficient  
conditions for membership  
Defining features

## Basic level categories are psychologically “privileged”

(Rosch & Mervis, 1975)

superordinate levels  
have an average of  
3 attributes

basic levels have an  
average of 9 attributes

subordinate levels  
have an average of  
10.3 attributes

moving up a level in the hierarchy  
loses a lot of information  
moving down a level gains only a little

### *How is knowledge organised in a hierarchical network?*

Principles of  
Property Inheritance  
Concepts “inherit” the properties of  
“parent” concepts in the hierarchy

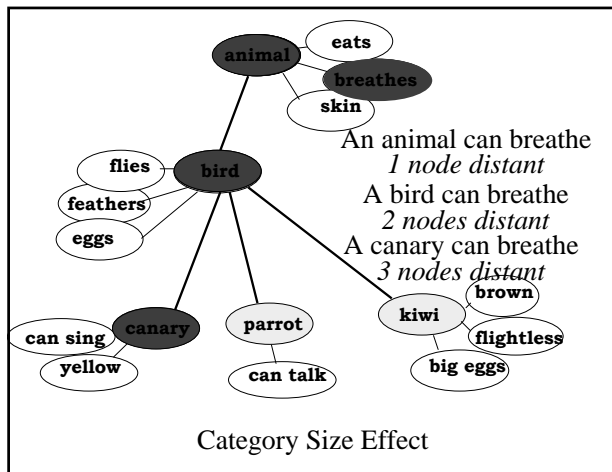

Cognitive Economy  
Information is stored once, at the highest possible  
node in the hierarchy (saves space)

e.g., Properties true of all animals  
(*have skin, breathe, eat, move*)  
are stored at animal node rather than  
with specific type of animal

### *How is information accessed in a hierarchical network?*

Intersection search  
traversing the hierarchy (up and down)  
takes time to move between levels  
Cognitive economy and intersection search  
principles predict the Category-Size Effect

*A canary can breathe*  
takes longer to verify than  
*A bird can breathe*  
which takes longer than  
*An animal can breathe*

### *But...*

The Typicality Effect  
typical members of the category are responded to  
more rapidly than atypical members  
(Smith et al, 1974)

*"An ostrich is a bird"*  
takes longer to verify than  
*"A canary is a bird"*

According to the hierarchical model, this  
shouldn't happen because ostriches and  
canaries are at the same level  
(one node away from bird)

### *But wait, there's more...*

*A pig is an animal*  
is verified more rapidly than  
*A pig is a mammal*

The Category-size effect is affected by the frequency  
with which a property is paired with a concept

*A bird has feathers*  
is verified more rapidly than  
*A bird has toenails*

because feathers are more frequently  
associated with birds than are toenails

### *But wait, there's even more...*

Some properties may be stored  
at multiple levels (no cognitive economy)  
(Conrad, 1972)

Free association task *"Write down as many  
things about canaries that come to mind"*

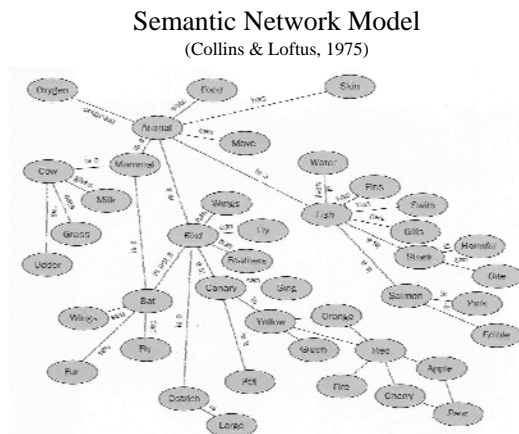

*Canaries are yellow*  
*Canaries have*  
*feathers* *Canaries sing*  
*Canaries can fly*  
*Canaries lay eggs*

Bird-level properties  
sometimes get named  
before canary-level  
properties

(Collins & Loftus, 1975)

Typical members stored more closely to the category name or prototype member

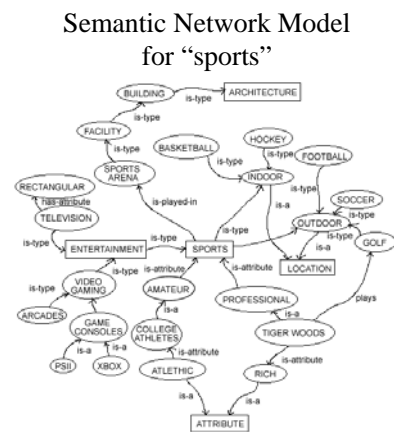

### Network searched via Spreading Activation

```

graph TD
    LANDSTRUCTURE[LAND STRUCTURE] -- is-type --> MOUNTAIN[MOUNTAIN]
    MOUNTAIN -- is-done-on --> ROCKCLIMBING[ROCK CLIMBING]
    ROCKCLIMBING -- is-type --> ATHLETICACTIVITY[ATHLETIC ACTIVITY]
    ATHLETICACTIVITY -- is-a --> SPORT[SPORT]
    SPORT -- is-a --> LINEDANCING[LINE DANCING]
    LINEDANCING -- is-a --> BALLROOMDANCES[BALL ROOM DANCES]
    ENTERTAINMENT[ENTERTAINMENT] -- creates --> MUSIC[MUSIC]
    MUSIC -- is-type --> SINGING[SINGING]
    ENTERTAINMENT -- is-type --> DANCE[DANCE]
    DANCE -- is-type --> CIRCLEDANCE[CIRCLE DANCE]
    DANCE -- is-type --> CHAINLINK[CHAIN / LINK]
    DANCE -- is-type --> FARANDOLE[FARANDOLE]
    CIRCLEDANCE -- is-a --> RING[RING]
    CIRCLEDANCE -- is-a --> CAROLE[CAROLE]
    CHAINLINK -- is-a --> RING
    CHAINLINK -- is-a --> CAROLE
    CHAINLINK -- is-a --> HORA[HORA]
    CHAINLINK -- is-a --> HORO[HORO]
    CHAINLINK -- is-a --> BULGARIA[BULGARIA]
    HORA -- is-created-in --> BULGARIA
    HORO -- is-created-in --> BULGARIA
    BULGARIA -- is-a --> COUNTRY[COUNTRY]
  
```

The diagram illustrates a hierarchical network of concepts. At the top level, 'LAND STRUCTURE' (box) is related to 'MOUNTAIN' (oval) via 'is-type'. 'MOUNTAIN' is related to 'ROCK CLIMBING' (oval) via 'is-done-on'. 'ROCK CLIMBING' is related to 'ATHLETIC ACTIVITY' (oval) via 'is-type'. 'ATHLETIC ACTIVITY' is related to 'SPORT' (oval) via 'is-a'. 'SPORT' is related to 'LINE DANCING' (oval) via 'is-a'. 'LINE DANCING' is related to 'BALL ROOM DANCES' (oval) via 'is-a'. 'ENTERTAINMENT' (box) is related to 'MUSIC' (oval) via 'creates' and to 'DANCE' (oval) via 'is-type'. 'MUSIC' is related to 'SINGING' (oval) via 'is-type'. 'DANCE' is related to 'CIRCLE DANCE' (oval), 'CHAIN / LINK' (oval), and 'FARANDOLE' (oval) via 'is-type'. 'CIRCLE DANCE' is related to 'RING' (oval) and 'CAROLE' (oval) via 'is-a'. 'CHAIN / LINK' is related to 'RING' (oval), 'CAROLE' (oval), 'HORA' (oval), 'HORO' (oval), and 'BULGARIA' (oval) via 'is-a'. 'HORA' and 'HORO' are related to 'BULGARIA' via 'is-created-in'. 'BULGARIA' is related to 'COUNTRY' (box) via 'is-a'.

## Prototype Theory

a prototype is the representation of the average instance of the category

Category membership is determined by “*family resemblance*” based on characteristic features (Rosch & Mervis, 1975)

## Focus on Characteristic Features instead of Defining Features

## Exemplar Theory

Instead of comparing to a single prototype  
we compare to multiple exemplars  
(Estes, 1994; Ross & Spalding, 1994)

Decision times are still determined by similarity  
to *characteristic features*

but abstraction occurs *during retrieval*  
instead of encoding

## Exemplar Theory

Is it a dog?

Compare to stored  
exemplars

Derive prototype  
if required

Ans: It's a dog

(Add to exemplars)

## Feature Comparison Theory

(Smith, Shoben, & Rips, 1974)

Knowledge is stored as a set of feature lists:

defining features

(necessary for membership--e.g., "feathers" for birds)

characteristic features

(typical, but not necessary--e.g., "sing" for birds)

## Feature Comparison Theory

Two-stage comparison process

### Stage One

Compare instance and category on all features  
(characteristic and defining)

If high degree of overlap, respond "true"

If low degree of overlap, respond "false"

### Stage Two

If moderate degree of overlap, proceed to  
second stage and check defining features only

## Feature Comparison Theory

Two-stage comparison process

Fast decisions with high degree of overlap

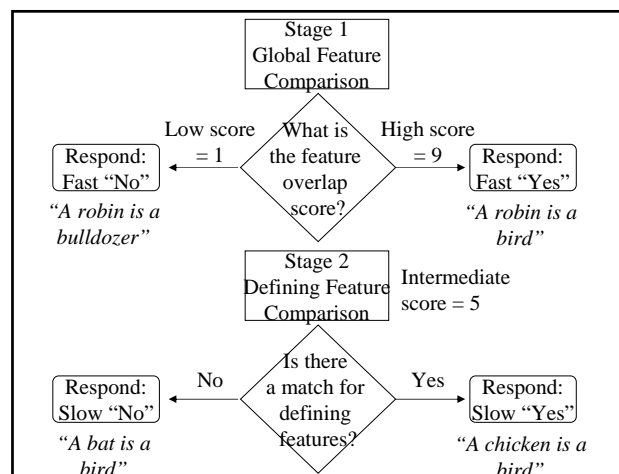

*A canary is a bird*

Canary matches both defining and  
characteristic features of bird

Second stage required with moderate overlap

*An ostrich is a bird*

Ostriches have few characteristic features but do  
fit defining features of a bird

### Feature Comparison Theory

Predicts Typicality Effects

*positive and negative*

e.g., *A whale is a fish*  
takes longer than  
*A horse is a fish*

*Whale* shares characteristic features with *fish*  
therefore leading to high degree of overlap and long  
“*No*” response times

*But...*

How are “*features*” determined?

e.g., what are the features of a “game”?  
(Wittgenstein’s famous argument)

Compare soccer, poker, hopscotch, “I spy”,  
solitaire, cat’s cradle....

Prototype & Exemplar Theories also both  
account for Typicality Effects but Exemplar  
Theory is a better match to human performance

The relationship between stored facts (memories) is  
every bit as important as the facts themselves

**Organisation matters !!!**

This week's laboratories  
finish the experiment on  
*Organisation as an aid to memory*

Remember: Quiz in labs next week!

Questions?
